ABSTRACT

Gray & Pape, Inc., of Houston, Texas, on behalf of Lonestar NGL Pipeline, LP, conducted an intensive pedestrian cultural resources survey within permitted areas of the 117.85-kilometer (73.23-mile) long Lone Star Express II Pipeline Project – Loop 2, in Nolan, Taylor, Callahan, and Eastland Counties, Texas. The lead agency for the project has been identified as the United States Army Corps of Engineers, Fort Worth District (Permit No. SWF-2019-00234). Thus, survey efforts concentrated on areas anticipated to be under the jurisdiction of the United States Army Corps of Engineers (permit areas). Within Loop 2, the total Area of Potential Effects within the permit areas measures approximately 125.9 hectares (311 acres). This area encapsulates approximately 29 kilometers (18 miles) of the proposed project alignment. The procedures to be followed by the United States Army Corps of Engineers to fulfill the requirements set forth in the National Historic Preservation Act, other applicable historic preservation laws, and Presidential directives as they relate to the regulatory program of the United States Army Corps of Engineers (33 CFR Parts 320-334) are articulated in the Regulatory Program of the United States Army Corps of Engineers, Part 325 - Processing of Department of the Army Permits, Appendix C - Procedures for the Protection of Historic Properties.

All fieldwork and reporting activities were completed according to a scope of work submitted to the United States Army Corps of Engineers and the Texas Historical Commission and accepted standards set forth by the Texas Historical Commission and the Council of Texas Archeologists and in accordance with Section 106 of the National Historic Preservation Act.

A records and literature review of the project location prior to the survey identified 17 previously recorded archaeological resources, one cemetery, one historic marker, and 17 previously conducted surveys within a 0.8-kilometer (0.5-mile) radius of the Loop 2 segment. Of those, six recorded archaeological resources are within 91 meters (300 feet) of the project corridor and four previous surveys intersect the project alignment. Fieldwork on Loop 2 was initially conducted in Spring 2019, with supplemental investigations taking place in August, October, and November of 2019. Survey of Loop 2 required approximately 2,320 person-hours to complete and involved archaeological reconnaissance and shovel testing throughout anticipated permit areas within the project corridor. In total, approximately 677 shovel tests were excavated within permit areas and beyond in cases of site delineation, of which six within the APE were positive for cultural materials. A total of 14 mechanical auger tests were conducted within Permit Area 6 at Mulberry Creek. All were negative for cultural materials.

Five previously recorded resources: 41NL318, 41TA353, 41TA354, 41TA314, and 41CA27; six new resources: 41TA396, 41TA397, 41TA398, 41TA399, 41CA42, and 41CA43; and two isolate finds were identified within Loop 2 permit areas. Materials were identified adjacent to one additional previously identified resource, 41TA371, located outside of Project Permit Areas. The material consisted of only two artifacts found on the surface in a disturbed context. Thus, the site was not expanded into the current Area of Potential Effects.

Four resources are of a historic age or have a historic component: 41NL318, 41TA396, 41TA397, and 41TA399. Historic components generally consist of early to mid-twentieth century and twentieth-century materials representative of trash dumps. Site 41NL318 contains a remnant of a private drive/road and associated wooden bridge. The remainder of the resources are prehistoric. Prehistoric site contents consist nearly entirely of surface scatters of artifacts, with artifact classes largely the same across each, consisting mainly of debitage, with varying numbers of cores and bifaces. On very few occasions, a

preform or utilized flake were also observed. In general, the resources appear to represent raw material procurement areas due to the abundant chert deposits available in the rocky soil. Activities are believed to have been largely limited to the procurement and testing of cobbles and expedient manufacture of bifaces. It appears that more refined tool manufacture was taking place elsewhere. Resources 41NL318, 41TA353/354, 41TA396, and 41TA314 contained the only diagnostic prehistoric artifacts identified during survey. Site 41TA353/354 contained Elam and Carrollton type projectile points and Site 41NL318 contained a Clear Fork Uniface, all of which can date to the middle to transitional Archaic. Sites 41TA396 and 41TA314 each contained a likely Marshall dart point which dates to the Late Middle Archaic. No artifacts were collected. No cultural features or historic-age standing resources were encountered in the field. The resource areas identified within the pipeline survey corridor have been previously disturbed by adjacent pipeline construction. Shovel test results at nearly all permit areas identified subsoils, cemented soils, or bedrock and gave indications of soil deflation or truncating, erosion, and past land modifications such as terracing and grading.

Mulberry Creek in Taylor County, Permit Area Number 6, was targeted for deep testing based on geomorphological data, and field results and discussions with the Field Archaeologist. Deep test results indicated a lack of A horizon soils and showed no potential for deeply buried cultural material or paleosols within the anticipated depth of impacts at the location.

Based on the overall lack of soil deposition, few diagnostics, and lack of integrity, it is the opinion of Gray & Pape, Inc. that the portions of recorded resources that are located within the proposed right-of-way do not retain the potential to provide significant research value and are thus recommended not eligible for the National Register, under Evaluation Criterion D or for State Antiquities Landmark status. Gray & Pape, Inc. recommends no additional archaeological work for these resources or surveyed permit areas of the project. However, Gray & Pape, Inc. recommends that an unanticipated discoveries plan be put into place in the event that such discoveries take place during construction.

1.0 INTRODUCTION

EDGE Engineering and Science, LLC (EDGE) of Houston, Texas, contracted with Gray & Pape, Inc. (Gray & Pape), of Houston, Texas, and Horizon Environmental Services, Inc. (Horizon) to perform an intensive pedestrian cultural resources survey within portions of the Area of Potential Effects (APE) of the Lone Star Express II Pipeline Project-Loop 2, located in Nolan, Taylor, Callahan, and Eastland Counties, Texas.

The lead agency for permitting purposes has been determined to be the United States Army Corps of Engineers, Fort Worth District (Corps or USACE). Thus, survey efforts were conducted within portions of the APE anticipated to be within Corps permit areas. The procedures to be followed by the USACE to fulfill the requirements set forth in the National Historic Preservation Act (NHPA), other applicable historic preservation laws, and Presidential directives as they relate to the regulatory program of the USACE (33 CFR Parts 320-334) are articulated in the Regulatory Program of the USACE, Part 325 - Processing of Department of the Army Permits, Appendix C - Procedures for the Protection of Historic Properties. All fieldwork and reporting activities were completed with reference to standards set by the Texas Historical Commission (THC) and the Council of Texas Archeologists (CTA). Loop 2 is located on private property. The following report includes the results of the archaeological survey completed within anticipated permit areas along approximately 117.85 kilometers (73.23 miles) of centerline in Loop 2.

1.1 Project Overview

Lone Star NGL Pipeline, LP (Lone Star), proposes to construct a new pipeline loop in Nolan, Taylor, Callahan, and Eastland Counties, Texas, referred to as the Lone Star Express II Pipeline Project – Loop 2 (LSXII – Loop 2 or Project). The LSXII – Loop 2 Project will be approximately 117.85 kilometers (73.23 miles) long and will be used to transport natural gas liquids (NGL). The purpose of the proposed Lone Star Express II Pipeline Project is to add approximately 400,000 barrels per day of NGL capacity to the existing Lone Star Express system which will help alleviate infrastructure constraints out of the Delaware and Permian basins in West Texas. The proposed Loop 2 portion of the Project will increase system capacity between the existing LSX2 Pump Station in Nolan County and the existing LSX3 Pump Station in Eastland County, Texas. The proposed pipeline loop will generally be constructed within existing utility corridors and has been designed to parallel the existing Lone Star Express I Pipeline. New permanent facilities will be constructed alongside the existing Lone Star Express Pipeline facility locations where possible. Construction is currently scheduled to begin on September 1, 2019. The anticipated in-service date for is January 2020.

Loop 2 intersects 11 USGS 7.5-minute topographic quadrangle maps (Figure 1-1, Table 1-1). Loop 2 begins approximately 16 kilometers (9.94 miles) east-southeast of Sweetwater in Nolan County and continues southeast approximately 117.85 kilometers (73.23 miles) through Taylor, Callahan, and Eastland Counties before terminating approximately 13.25 kilometers (8.24 miles) south-southwest of Cisco in Eastland County. Along the path of Loop 2, the APE is largely collocated with an existing pipeline corridor and intersects several major and county roads, unimproved roads, and agricultural fields. The anticipated Corps Permit Area/APE for Loop 2 consists of approximately 125.9 hectares (311 acres) encapsulating approximately 29 kilometers (18 miles) of Project centerline. The breakdown of area/length per county is provided in Table 1-2. Loop 2 also crosses approximately 35 natural waterways (Table 1-3).

1.2 Report Organization

This report is organized into seven numbered chapters and six lettered appendices. Chapter 1.0 provides an overview of the Project. Chapter 2.0 presents an overview of the environmental setting and geomorphology. Chapter 3.0 presents a discussion of the cultural context associated with the APE. Chapter 4.0 presents the research design and methods developed for this investigation. The results of this investigation are presented in Chapter 5.0. Chapter 6.0 presents the investigation summary and provides recommendations based on the results of field survey. A list of literary references cited in the body of the report is provided in Chapter 7.0. Maps of the field survey coverage for Loop 2 are displayed in Appendix A. Maps illustrating shovel test coverage in Permit Areas is displayed in Appendix B, however for more detailed test coverage of cultural resources see the individual site plan maps provided within the body of the text in Chapter 5.0. Appendix C contains a log of all excavated shovel tests.

Appendices D through F contain condensed versions of deed research documentation for the properties containing cultural resources 41TA396, 41TA397, and 41TA399.

1.3 Acknowledgements

Fieldwork on Loop 2 was conducted from April 2 to May 2019, with supplemental investigation taking place on August 6, from October 1 to 13, and again November 5 and 6, 2019. required approximately 2,320-person hours to complete. The Project was managed by Senior Principal Investigator Tony Scott. Field activities within Loop 2 were conducted by Gray & Pape Field Leaders Marcia Vehling, Chris Baltz, Monte Lawton, Charlie Rose, Kyle Mayer, and Jacob Hilton. Field Technicians included Amanda Kleopfer, Hilda Torres, Robert Beckwith, Marie Swartz, Katrina Miller, Kaitlin Roberts, Steven Sykes, Petrina Kelly, Kyle Potter, and Luis Gonzalez. Field efforts were also conducted by Horizon Field Leader Elizabeth Sefton and Field Technicians McKinzie Froese, Dan Cambiano, Foster Duncan, and Steven Schooler under the guidance of Horizon Project Manager Jesse Owens. The report was prepared by Tony Scott, Hilda Torres, Amanda Kleopfer, and Ryan VanDyke. Prehistoric and Historic artifacts analysis was performed by Gray & Pape Lab Supervisor Eric Edelbrock and Lab and Curation Specialist Jacob Hilton. Architectural Historian Ryan VanDyke performed archival research for properties containing identified historic sites. Graphics were produced by Tony Scott. Jessica Bludau edited and produced the report.

Gray & Pape extends a special thank you to Lone Star Construction Manager Mike Churchman, Assistant Construction Manager Clyde McDonald, and Pipeline Inspectors Bill Laird, Shane Holdridge, Mark Salmon, and Patrick Hill, whose assistance and knowledge was instrumental in the timely and safe completion of the survey effort.

2.0 ENVIRONMENTAL CONTEXT

2.1 Physiography and Geomorphology

Most of the Project is situated in the North Central Plains area of the Interior Plains physiographic region. Nolan, Taylor, and Callahan Counties are characterized by the North Central Plains Physiographic region. The rolling terrain was created by the effects of erosion from ancient streams, leaving a landscape that is also steeply sloped in areas of highly dissected riverine edges (Bureau of Economic Geology [BEG] 1996). The northern portions of Nolan County consist of rolling uplands, while the southern areas contain plateaus intersected by valleys (Texas State Historical Association [TSHA] 2019). Taylor County is characterized by nearly level sloping plains and escarpments which separate it from the Edwards Plateau (Natural Resource Conservation Service [NRCS] 2019). Callahan County is split east-west by the Callahan Divide which separates the watersheds of the Brazos and Colorado Rivers (TSHA 2019). A portion of southeast Callahan County lies within the Edwards Plateau natural region and has undulating to hilly grassy plains which slope eastward (NRCS 2019). Eastland County lies within the Grand Prairie Physiographic region. The southern part of the county contains a rolling sandy surface, while the northern and east-central regions have a broken hilly morphology (NRCS 2019).

2.2 Surface Geology

Loop 2 crosses 18 geological formations (Table 2-1). The surface deposits across the length of Loop 2 primarily consist of Permian-age mudstone or shale underlain by limestone, mudstone, sandstone, or siltstone.

Table 2-1. Geologic Groups/Formations Intersected by Loop 2.

Label	Formation/Group	Age	Rock Type 1	Rock Type 2
Ka	Antlers Sand	Early Cretaceous	sand	clay or mud
Pad	Admiral formation	Permian; Wolfcamp Series	mudstone	limestone

Pta	Talpa Formation	Permian; Leonard Series	shale	limestone
Qal	Alluvium	Holocene	sand	silt
Qu	Quaternary Deposit, undivided	Quaternary	sand	silt

2.3 Soils

Loop 2 intersects approximately 80 soils spread across the four counties (United States Department of Agriculture – Natural Resources Conservation Service, Soil Survey Office [USDA-NRCS SSO] 2008). Loop 2 is represented by the Tillman-Vernon-Hollister and Windthorst-Chaney-Duffau soil associations (BEG 2008). Tillman-Vernon-Hollister association is generally characterized as reddish well-developed soils that can be moderately deep before transforming into sandstone and mudstone bedrock (USDA-NRCS SSO 2008). Windthorst-Chaney-Duffau association forms on rolling landscapes that are covered with Cretaceous age sandstone, shale, and limestone outcrops. Duffau and Windthorst soils are deep, highly weathered soils that are highly susceptible to erosion. Chaney soil is characterized by deep clayey subsoils that transform into claystone or shale (USDA-NRCS SSO 2008).

The soils in Nolan County are dark brown with very gravelly clay loam over cracked limestone bedrock in the rangelands. Soils of the uplands are grayish brown with gravelly clay loam overlying white caliche. The hills and ridges have calcareous reddish-brown loam over red mottled sandstone (NRCS 2019). Taylor County has loamy surface soils that are reddish to brownish over clayey subsoils that have accumulated lime (TSHA 2019). Callahan County soils are a light to dark loam with clayey to loamy subsoils, although the soils in the southeast portion of the county are light with loamy to sandy surface layers and clayey subsoils (TSHA 2019). Eastland County's soils are loamy sand underlain by sandy clay in the uplands which are dissected by numerous streams and drainages. The soils of the ridgetops and hillsides are shallow with stony sandy loam over clay, sandy clay, and sandstone or limestone (NRCS 2019).

2.4 Natural Environment

Most of the Project area is characterized by the scrub brush and grasslands of the Rolling Plains (BEG 2000). In some places, however, the scrub brush and grasses are entirely replaced with agricultural crops (BEG 2000). Local plants include buffalo grass, various short grasses, juniper, and mesquite. Wildlife include the critically endangered lesser prairie chicken, as well as mammal species such as deer, fox, raccoon, skunk, opossum, badger, ringtail cat, bobcat, coyote, and peccary (Griffith et al. 2007). Other species inhabiting the area include waterfowl, rattlesnake, raptor, and jackrabbit (Lowther 1981). Loop 2 lies within the Kansan biotic province which contains grassland species, along with some Austroriparian species (Blair 1950).

2.4.1 Climate

The western portion of the Project area has a semi-arid climate that becomes subhumid in the eastern areas. Rainfall is typically less than 71 centimeters (28 inches), most of which falls during spring and early summer storms. Summer temperatures can be intense, but a large diurnal range and low humidity results in relatively cool evenings, even in the hottest times of the year. Winters are generally mild with occasional light snowfall, but sudden drops in temperature can vary (Moore 1977; Conner 1976; Clower 1981; Lowther 1981).

2.5 Land Use

Land use is largely agricultural throughout the Project area. A small portion of Loop 2 crosses a suburban area on the outskirts of Abilene in Taylor County. Portions of the Project not used for agriculture are generally covered by grasses and scrub brush. Much of the Project length is collocated and shows clear signs of disturbance from adjacent pipeline corridors and supporting infrastructure.

3.0 CULTURAL CONTEXT

3.1 Prehistoric Context

Prehistoric sites in the Southern High Plains and Central Plains regions are commonly found on the surface and in mixed context (Meltzer 1987). Sites are typically located along the remnants of draws, playas, and larger salina basins that have been filled in by eolian processes (Johnson and Holliday 2004). The majority of known prehistoric Clovis, Folsom, and Late Paleoindian archaeological sites in Texas are found in portions of the High Plains region near New Mexico and western Oklahoma. The general area was near the southernmost reach of now extinct megafauna in the United States and included mammoth and a large form of bison, which were frequently hunted by prehistoric groups.

Sites with historic components in the region date as far back to the 1700s as was recorded in Blanco Canyon. Most historic sites in the area represent materials left behind by Hispanic sheepherders called *pastores*, European buffalo hunters, military outfits, and Anglo dumpsites (Perttula 2004).

Archaeological materials that have contributed to the development of a five-period cultural chronology, as developed by Kelley (1964) and Prikryl (1990) in the area based on excavations at a handful of intact sites. For the purpose of this report an attempt is made to generalize these periods in the following paragraphs; however, it should be noted that cultural periods are not equally represented across the varying ecological and physiographic areas that the Project intersects.

3.2 Paleoindian Period

The Paleoindian period falls within the latter part of the Pleistocene and into the early Holocene. It is generally agreed to have begun as far back as 11,500 years before present (B.P.) and continued until 8,500 B.P. and is marked by ubiquitous hunting and on-site butchering of megafauna in small nomadic groups.

The Paleoindian period is further subdivided into three more specific periods marked by projectile point technologies (Frison 1991; Holliday 1997; Wheat 1972; Wormington 1957). These include the well-known Clovis, Folsom, and Late Paleoindian periods. The Clovis period is thought to have endured at least 500 years during the latter part of the Pleistocene and its lithic technology is the oldest known in North America. Clovis points are lanceolate-shaped with short flutes (Turner and Hester 1993). Clovis points are large, heavy, and well-made tools that were used for puncturing the thick flesh of large game. The Folsom period, from 10,800-10,300 B.P., is also defined by a large fluted lanceolate-shaped point. Folsom points look similar to the Clovis point, but are thinner, more symmetrical, evenly chipped on the edges, and have a single classic flute all the way up the center of the point (Turner and Hester 1993). The Late Paleoindian period, from 10,000-8,500 B.P, is characterized by excellent craftsmanship of long, thin, narrow, lanceolate points without flutes. Instead, these points have parallel flakes and are ground with thinned bases typically accomplished with a few vertical flakes (Turner and Hester 1993). Paleoindian sites of note located in the Southern High Plains and Central Plains regions include the Lone Wolf Creek (41MH23), Midland (41MD1), and McClean (41TA29) sites.

3.3 Archaic Period

Following a transition to a warmer climate, the Archaic period is accepted to have lasted between 8,500-1,250 B.P. The Archaic period is marked by an adaptation to less abundant water resources and to more dependence on vegetation as a food source than compared to people living in the Paleoindian period

(Johnson and Holliday 2004). The Archaic period is further subdivided into two periods, known as the Early and Late Archaic periods, which the former is characterized by a lack of occupational sites in the area during a time called the Altithermal when the land was hot, dry, and dusty. The Late Archaic is defined by a sudden increase in the number of sites around 4,500 B.P., when a noticeably milder climate with less hostile conditions returned to the area (Antevs 1954; Hughes 1991). Archaic sites are commonly associated with fewer megafauna kill sites than earlier Paleoindian sites. Such sites are often associated with an array of stemmed and later barbed dart points, ground stones, and hearths lined with burned stone and caliche-cobbles (Hofman 1989).

3.4 Late Prehistoric Period

The Archaic period was followed by the development of ceramic technology and the bow and arrow. These two inventions made way for significant sociocultural changes including a shift toward sedentism and decreased mobility. These developments are the hallmarks of the Late Prehistoric period, which lasted from A.D. 200-1450.

Because of more specific diagnostic traits associated with the Late Prehistoric, it is further subdivided into the Woodland period (A.D. 200-1450), the Palo Duro Complex (A.D. 500-1100), and the Antelope Creek Phase (A.D. 1200-1450). The Lake Creek Site in the Texas Panhandle represents the Woodland Period in the High Plains, which is characterized by cordmarked ceramics, corner-notched Scallorn arrow points, and a large assemblage of lithic flake tools (Hughes 1962). Palo Duro Complex Sites are defined by the use of pit houses and evidence of plant food procurement and processing. The first evidence of such was gathered during excavations by Willey and Hughes (1978) of the Deadman's Terrace Site, more commonly called Deadman's Shelter.

Finally, the Antelope Creek Phase, sometimes called the Antelope Creek Focus, is the most distinctive and well-known of the Late Prehistoric periods in the Panhandle. Hughes (1991:31) documents the highest density of Antelope Creek Sites occurring along the Canadian breaks. Antelope Creek sites are best known by their pueblo-like structures with numerous rooms. These sites are also commonly identified by the presence of bone tools, made from butchered bison, scrapers, grinding slabs for plant processing, and sometimes obsidian (Hughes 1991).

3.5 Protohistoric Period

The Protohistoric period dates from A.D. 1450 to AD 1600. It is defined by documented trade activities with neighboring Pueblos, increased ceramic production projectile points that seem to be confined to one of two subdivisions of the Protohistoric. The Tierra-Blanca Complex and the Garza Complex are contemporary. The Tierra-Blanca Sites are thought to have traded with the New Mexico Pueblos and are typically identified by the presence of larger villages (Hughes 1991). The Garza Complex is associated with the Garza point type which seems to only appear at Garza Complex sites. Other point types found at Garza Complex sites include the Washita, Harrell, Lott, and Fresno (Hughes 1991).

3.6 Historic Period

Several Native American tribes are known to have inhabited the area prior to Spanish contact in 1541; these include the Apache, Comanche, Kiowa, and Kiowa-Apache (Newcomb 1961). In the nineteenth century, the area was inhabited by the Kiowa and Comanche tribes, who preferred free range over Oklahoma's reservations (Whitlock 1970). By then, the Comanche had displaced the Apache. It is widely known that by the nineteenth century, aboriginal groups remaining in the High Plains had begun exploiting horses for use during hunting and raiding. During that time, the Comanche were assigned by the Army to reservation life in Oklahoma (Newcomb 1961).

3.7 Historical Context of the Region

The earliest written descriptions of the north-central region of Texas come as a result of Spanish exploration of the areas to the north and west of the current Project. The cliff on the north facing of the Canadian River was seen by Francisco Vásquez de Coronado in 1541 on his way east from Cíbola, leading him to name the plateau the Llano Estacado, or *Palisaded Plain*. In addition to recording the initial explorations of the Llano Estacado, Coronado developed the region's orientation toward the Hispanic Southwest. Coronado's efforts were mimicked by Juan de Oñate during an early seventeenth century expedition along the Canadian River. In 1872, the Llano Estacado was described by General Randolph Marcy as a "great North American desert" with "not a tree, bush or water" (Whitlock 1970).

At the time, buffalo herds were common across the Llano Estacado. In the 1870s, conflict between American buffalo hunters and regional Native-American tribes reached its apex in the Red River War. Military defeat and the slaughter of the buffalo herds forced the Comanches, Kiowa, Cheyenne, and Arapaho off the plains to reservations (Haley 2010).

White settlement in the region remained sparse early on due to risk of hostilities with tribes such as the Comanche. Large cattle ranches and agriculture (mainly cotton) became the primary industry in the region with subsequent booms and bust within the petroleum and natural gas industries continuing to be the major driver of development of the region into the present day (Long 2010).

4.0 FIELD METHODOLOGY

This cultural resource investigation was designed to identify and assess new and previously recorded cultural resources that may be impacted by the proposed Project. Desktop assessment and modeling were performed prior to initiating field investigations to better understand cultural, environmental, and geological settings. Results of the desktop assessment were then used to develop the field methodology.

4.1 Site File and Literature Review

The background literature search included a review of previously conducted cultural resource surveys in the vicinity of the proposed Project area, and of any historic document pertaining to the history of the area. Site file research was performed to identify all previously recorded archaeological sites within a 0.8-kilometer (0.5-mile) study radius of the Project area and any recorded historic structures eligible for the National Register of Historic Places (NRHP) or State Antiquities Landmark (SAL) listing located adjacent to the Project area. Site file research was done by reviewing records maintained by the Texas Archeological Research Laboratory in Austin, Texas, and by consulting THC.

Historical topographic maps and aerial photographs when available were reviewed to identify any historic structures, residential, and other structures that might be located close to or within the Project area. Historical maps of Texas and Texas counties were also reviewed in order to better understand the history of the region and to identify any potential historic trails and important historic sites located or crossing the Project area.

4.2 Field Methods

4.2.1 Intensive Pedestrian Survey

The Project was subjected to pedestrian survey within permit areas. Permit areas were based on water features which were field delineated by biological field crews in conjunction with the cultural resource survey. The permit areas for each water feature were assessed on a case-by-case basis but in general comprised the first terrace to first terrace of large perennial creeks and rivers that intersect the APE. For smaller streams and water features without terraces, a minimum baseline buffer area placed to either side of the water feature was assessed. These buffer areas consist of 180 linear meters (600 linear feet) to either side of larger perennial and intermittent drainages and 100 linear meters (300 linear feet) to either side of some intermittent and ephemeral drainages, wetlands, and catch basins. Based on the project's typical corridor width of 39.6 meters (130 feet), two transects were investigated, with additional transects added as needed for wider temporary workspaces. Transects were spaced no more than 30 meters (100 feet) apart. Because most of the project APE is collocated with an existing pipeline corridor, which at times subsumes half or more of the total corridor width, one survey transect was often within an existing pipeline easement. Existing easements were routinely maintained and often displayed greater than 70 percent surface visibility. Survey transects overlapping existing easements, excessive slope, or standing water were at a minimum subjected to pedestrian surface inspection/walkover, and also judgmentally shovel tested where warranted to confirm/refute suspected subsurface disturbance. Digital photography aided documentation of the existing conditions of the Project area and fieldwork methods, with photograph locations recorded on field maps and logged with a Global Positioning System (GPS) unit.

Shovel testing within permit areas was attempted along each transect at a number which met or exceeded Texas State Minimum Archaeological Survey Standards regardless of surface visibility. Shovel tests were generally spaced at intervals between 30 and 60 meters (100 and 200 feet). In areas of clear previous disturbance or areas of lower probability for

cultural resources, shovel tests were not typically conducted at a distance greater than 100 meters (328 feet). Shovel tests were attempted to depths of 1 meter (3.3 feet) or until culturally sterile subsoil was reached, except where bedrock was present at shallow depths, or where potential existing pipelines were present.

All shovel tests measured approximately 30 centimeters by 30 centimeters (1 foot by 1 foot). When possible, all soil was screened through 0.64-centimeter (0.25-inch) wire mesh. Vertical control of each shovel test was maintained by excavating in arbitrary 10-centimeter (4-inch) levels with reference to the parent soil stratum. The profile of each shovel test was inspected for color and texture change potentially associated with the presence of cultural features. Descriptions of soil texture and color followed standard terminology and soil color charts (Munsell 2005). Additional information such as mottling, evidence of disturbance, and moisture level was also recorded. All shovel test data were recorded in one of two formats for analysis: 1) a GIS file which had the appropriate attribute columns set up for population in the field, or 2) standardized paper forms. All shovel tests were backfilled after excavation and documentation. The excavated shovel tests were placed on field maps and points were taken with a GPS unit.

At each permit area location, a summary of the results of activities along with recommendations was provided to the Principal Investigator on a daily basis. These summaries were then submitted to the client. At regular intervals while survey was in progress shovel test forms were submitted to the Principal Investigator for review. Any need for additional work such as deep testing was based on the field results in coordination with the Field Archaeologist and arranged with the client.

4.2.2 Deep Testing

As documented in Chapter 5.2 below, shovel test results in nearly all permit areas indicated deflated soils with subsoil or bedrock near the surface. This is likely due to previous erosion and disturbance as a result of previous pipeline installations, the existing ROW of which subsumes the majority of the current APE. However, the location of Permit Area Number 6 at Mulberry Creek in Taylor County was identified as a candidate for deep testing. This determination was based on geomorphological data, and field results and discussions with the Field Archaeologists. The location is mapped for Holocene-age alluvial deposits which have the potential for a deep A horizon. Shovel test results at the location could not confirm that subsoils were reached and as a result, deep testing for the location was advised by the Field Archaeologist. The methodology for deep testing was formulated in conjunction with agency coordination. Agency consultation concurred with the use of machine auguring at the location. Auger tests were placed at 50-meter (164-foot) intervals, conducted along a single transect placed outside of the existing pipeline right-of-way (ROW) for safety concerns. Mechanical auguring was conducted with reference to the most recent draft of the Council of Texas Archeologists (CTA) guidelines. Soil matrix removed during auguring was placed on plastic tarp to keep it separated from the surrounding vegetation. The removed material was monitored for texture and color changes and screened using ¼-inch mesh. Descriptions of soil texture and color followed standard terminology and the Munsell (2005) soil color charts. The locations of all deep tests were recorded with a sub-meter accurate GPS data collector and recorded on field maps.

4.2.3 Site Definition

Surface visibility along the entire Project length was generally 70 percent or greater. Thus, all previously recorded sites that intersect the APE within permit areas were subjected to surface inspection supplemented by a sample of shovel tests placed at regular intervals within the previously established site boundary to check for deposition and density. A minimum of six radial shovel tests were typically attempted conducted in cardinal directions around the site

boundary within the limits of the APE. Delineation tests were typically conducted in 10-meter (33-foot) intervals but increased or decreased at the Field Archaeologist's discretion based on contributing field factors such as surface expression, previously established site size, previous disturbance, landforms, amount of surface visibility, and perceived areas of surface density. Delineation tests were generally pursued until reaching two consecutive negative tests beyond the established site boundary.

Newly identified sites were delineated in the same manner. Positive shovel tests, artifacts visible on the surface, and site boundaries were recorded on Project maps and via sub-meter accurate GPS. Newly identified sites and revisited previously recorded sites were also documented on standardized archaeological site forms.

For each cultural resource identified, including structures or other resources within or immediately adjacent to the APE, photographs were taken of the general vicinity and of any visible features, if present. A sketch map was prepared showing site limits, feature locations, permanent landmarks, topographic and vegetation variations, sources of disturbances, and total number of tests performed within and near the site. Artifacts recovered from shovel tests were not to be collected. All discovered artifacts were photographed in the field and placed in the backfilled shovel test or left on the surface. Locations of all positive tests were recorded with the GPS.

Each identified resource was given a temporary field site number. Site forms were submitted for each cultural site identified. Revisit site forms were completed for previously recorded sites re-identified in the field. State-issued trinomial site numbers were requested for cultural sites but not for identified isolates.

If any architectural resources had been identified, these would have been recorded on corresponding field forms. Details of form, construction, material, style, condition, and alteration would be recorded both on the forms and photographically for each structure. All documentation would be reviewed by a qualified Architectural Historian who would decide if additional information or a personal field inspection was necessary at the survey level.

4.3 Archival Research

Historical research was conducted for three sites in Taylor County and one site in Nolan County, which were identified at the request of the USACE. A wide variety of sources, including historic maps, aerial photography, and local historic records were consulted. Gray & Pape reviewed historic topographic quadrangle maps, historic aerials, and Google Earth historic aerial imagery. Deed research was conducted at the Taylor County Clerk's Office for the three historical sites within Taylor County. In-depth deed genealogical research was conducted on the names of previous owners for each site. In addition, historical General Land Office Maps, atlas maps, Ancestry.com, Find-a-Grave.com, and United States Census Records were consulted.

4.4 Laboratory Analysis

4.4.1 Artifact Analysis

Artifacts encountered in the field were not collected; thus, no lab analysis was conducted. Artifacts were instead described and classified in the field as best as possible and representative samples were photographed. Data recorded in the field for uncollected artifacts included general attributes such as form (if identifiable), material, functional classification (if identifiable), and counts.

4.5 Curation

No diagnostic or non-diagnostic artifacts were collected in the course of the current survey. Gray & Pape will maintain Project records in their curation facility in Houston.

5.0 RESULTS OF INVESTIGATIONS

5.1 Result of Site File and Literature Review

A search of the Texas Archeological Sites Atlas, maintained by the THC, determined that no National Register properties intersect the Project alignment within Loop 2. The same research identified that 17 previously recorded archaeological sites, 17 previously conducted archaeological surveys, one historical marker, and one cemetery had been recorded within the 0.8-kilometer (0.5-mile) study radius of the Project area.

5.1.1 Previously Recorded Surveys

According to a search of the Texas Archeological Sites Atlas, at least 17 previous surveys have been conducted within a 0.8-kilometer (0.5-mile) study radius of Loop 2 (Table 5-1, Appendix A). Four of those surveys intersect the Project alignment; however, these consist of narrow survey corridors and none significantly overlap the current Project. The most recent of these surveys were conducted by Tetra Tech, AR Consultants, and Horizon. Projects included the Colorado City to Corsicana Pipeline and the BridgeTex North Pipeline. A review of reports associated with these and other surveys in the vicinity indicated a mix between 100 percent survey coverage and survey of USACE jurisdictional water crossings. Survey findings suggest that while archaeological sites are not uncommon in the general vicinity, they do not typically contain the information that would result in a recommendation for eligibility. Some of these resources are discussed further in-depth below.

5.1.2 Previously Recorded Archaeological Sites

Per a search of the Texas Archeological Sites Atlas, 17 previously recorded archaeological sites occur within the 0.8-kilometer (0.5-mile) study radius of the Project area. Those 17 resources, or at least portions of them, have been previously determined to be ineligible for listing on the National Register. Of those 17 resources, six are located within 91 meters (300 feet) of the Project APE (Table 5-2). Four of the resources that are potentially within permit areas were re-identified during survey and are described in greater detail in Section 5.2.2 of this report.

5.1.3 Historical Markers

One historical marker is recorded within 0.8 kilometers (0.5 miles) of the Project. Marker number 3343, entitled "Merchant Home" was established in 1962 (THC 2019). Historical marker 3343 is located approximately 290 meters (951.44 feet) north of the Project corridor at its closest (Figure A21). It is located approximately 7.57 kilometers (4.7 miles) south-southeast of Baird, Texas.

5.1.4 Cemeteries

Only one cemetery is located within the 0.8-kilometers (0.5-miles) radius of the Loop 2 Project area. Eula Cemetery (CA-C016) is located approximately 515 meters (1,689.63 feet) south of the project corridor at its closest (Figures A16/A17). Eula Cemetery (CA-C016) is located east of County Road 241 near Abilene, Texas, and contains approximately 815 memorials.

5.2 Results of Field Investigations

Fieldwork included archaeological reconnaissance throughout USACE permit areas of the APE. Crews from both Gray & Pape and Horizon conducted field survey. In total, 65 permit areas were surveyed (Table 5-3). These entailed approximately 120 water features consisting of streams, rivers, wetlands, and ponds/catch basins were tested. These areas included more than 160 different parcels. A total 677 shovel tests were excavated: 652 within permit areas and 25 during site delineation outside of permit areas. Of those, six were positive for cultural materials resulting in the re-identification of five previously recorded resources, the discovery of six new resources, and two isolate finds (arranged by milepost in Table 5-4). Artifacts that may be associated with one additional previously recorded resource were identified within the Project APE but outside of permit areas (Table 5-5). Resource and artifact descriptions are provided in more detail in Sections 5.2.2 to 5.2.5, below. For organization and to discern jurisdictional versus non-jurisdictional, and previous versus new resources, discussions of resources are broken into four categories with corresponding subsections: 5.2.2.) Re-identified Previously Recorded within Jurisdictional Areas; 5.2.3) Newly Recorded Resource within Jurisdictional Areas; 5.2.4) Newly Recorded Isolates within Jurisdictional Areas; and 5.2.5) Previously Recorded Non-Jurisdictional Resources. Each resource within each subsection is arranged in order along the along the alignment from west to east.

5.2.1 Loop 2 General Characteristics

Loop 2 extends throughout Nolan, Taylor, Callahan, and Eastland Counties. This portion spans approximately 117.85 kilometers (73.23 miles) and 1,077.64 hectares (2,662.91 acres).

The vicinity of the loop is split between pasture/scrub brush (Figure 5-1) and farmland (Figure 5-2). Surface visibility generally ranged from 70 to 100 percent. Almost the entire survey corridor has been previously impacted by pipeline installation, maintenance, or subsequent erosion, county roads, and unimproved roads that cross the APE. Within Loop 2, 677 shovel tests (see Appendices B and C). While the project intersects areas mapped for at least 80 soils series, permit areas most often intersected areas mapped for Pedernales, Sagerton, Chaney, and Cisco-Hext-Pedernales Association soils series. These soils typically have an A horizon below 30 centimeters (12 inches).

The typical shovel test profile for the loop consisted of reddish-brown clay or 7.5YR 4/4 sand followed by bedrock (Appendix C). The depth of the surface and subsurface layers was typically shallow (35 centimeters [13.78 inches]), indicating past impact by erosion or land modification. In most tests, these layers were underlain by bedrock. Because of this, very few tests approached 100 centimeters (33 inches). Approximately 108 shovel tests showed evidence of disturbance displayed as mottled soils containing larger quantities of calcium carbonate or gravels throughout. These tests typically were located within or very near the existing pipeline corridor limits.

5.2.2 Revisits of Previously Recorded Resources Located within Jurisdictional Areas

Five previously recorded resources that intersect the Loop 2 permit areas were re-identified during survey. The resources were re-identified by either Horizon or Gray & Pape crews. In some cases described below, Horizon performed the site investigation within the APE and Gray & Pape conducted delineation work outside of the APE to better define the site boundary. Results at each re-identified resource are described below. The sites are organized as they fall on the pipeline west to east.

Figure 5-1. Example of scrub brush vegetation coverage observed in Loop 2. View is to the southeast.

Figure 5-2. Example of agricultural areas observed in Loop 2. View is to the southeast.

5.2.2.1Resource 41NL318

Background/Previous Work

Resource 41NL318 was originally recorded in 2013 and 2014 by Tetra Tech, Inc. for the Permian Express Pipeline II survey (Karpinski et al. 2014). The resource was recorded as a small surface scatter representing a briefly-occupied resource procurement or processing camp. The resource was recorded on a low, eroded, gravelly ridge located adjacent to a pond formed from an unnamed tributary of Noodle Creek, approximately 70 meters (230 feet) west of County Road (CR) 222 (White Flat Road). The site includes the possible remnants of a hearth consisting of about 24 pieces of fire cracked rock (FCR) along with 150 pieces of lithic debitage. No diagnostic artifacts were identified within the site. The resource was found to be largely disturbed with erosion being the primary cause of disturbance. Additional impacts were contributed to artifact collecting, building of a cattle pond, adjacent farm road, and a nearby road-side refuse pile. The resource was not recommended for further work and was later determined to be ineligible within the pipeline ROW (THC 2019).

Current Investigation

Resource 41NL318 was revisited on April 9, 2019, by Horizon. The resource is located in Permit Area 1 to either side of CR 222. The site to the west of CR 222 is composed of two nearly level uplands dissected by an inlet of the adjacent pond. The site to the east of CR 222 rises sharply and contains two ridgetops within the ROW. The APE within the resource generally measures 40 meters (131 feet) wide with two areas of expanded workspace measuring approximately 47 meters (156 feet) wide. Of that amount, only approximately 30 meters (100 feet) of APE is located within an existing pipeline ROW. The site as originally mapped is now nearly completely within the existing pipeline ROW. No FCR or concentrations of FCR were observed at the original site location or in the expanded site area. The location within the existing ROW is sparsely covered by grasses with the ground surface visibility decreasing outside of the ROW (Figure 5-3). The area is currently being used as a cattle pasture and has been impacted by flooding, erosion, existing pipelines and berming for erosion control and the nearby man-made pond. The resource primarily consists of a surface scatter located to the east/south side of the tributary and pond.

Figure 5-3. Location of Site 41NL318. View is to the east.

Initial investigation by Horizon consisted of pedestrian walkover and shovel tests excavated at 30-to 60-meter (100-to 200-foot) intervals within the APE (Figure 5-4). Observed artifacts include approximately 30 flakes, tested cobbles, 3 crude bifaces, and one preform (Table 5-6; Figure 5-5). Of the eight shovel tests placed within and outside of the original resource boundary/APE, one was positive for a single chert flake observed at between 20 and 30 centimeters (8 to 12 inches) below ground surface.

GRAY & PAPE
HERITAGE MANAGEMENT

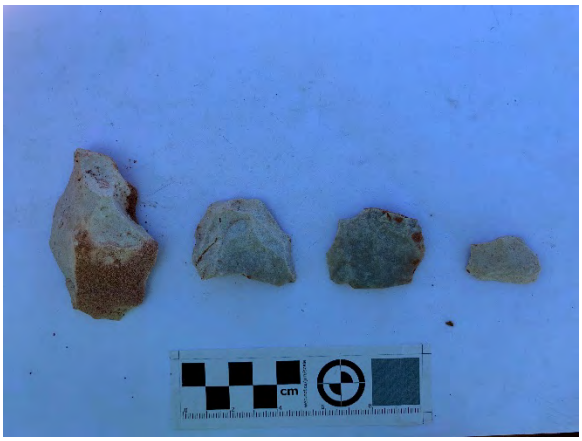

Figure 5-5. Representative materials identified on the surface within Resource 41NL318.

On April 16, 2019, Gray & Pape revisited the site to attempt to delineate the site limits to the north and south by surface inspection and shovel testing. Surface survey beyond the APE identified additional debitage and tested cores. Thirteen additional shovel tests were placed around the visible limits of the surface scatter outside of the APE. These tests were spaced between 20 and 30 meters (67 and 39 feet) apart due to the high visibility of the surface, erosion exposed subsoil visible at the surface, and observed landforms that the site occupies. Of the 13 additional shovel tests, none were positive for additional cultural materials.

The resultant resource is greatly expanded from the original site boundary and measures approximately 450 meters (1,500 feet) east-west by 180 meters (590 feet) north-south. Soils mapped for the location consist of Sagerton clay loam, Nipsum clay loam, Dermott soils, and Knoco clay (NRCS 2019). These soils typically have a shallow surface layer of brown (7.5YR 4/2) clay loam followed by a B horizon of brown (7.5YR 4/2) to reddish brown (5YR 5/4) clay. The soil is carbonate rich and impenetrable at shallow depths. A typical shovel profile within the resource/APE consists of a surface layer of red, dark brown, to reddish brown (5YR 4/4) clay to a depth of 20 to 30 centimeters (8 to 12 inches) followed by compact subsoil clay or bedrock (Appendix C). This suggests the location has experienced severe erosion and lacks an A horizon.

Agency Revisit

The site was revisited by Gray & Pape and representatives of the USACE on October 29, 2019. During a walk over of the portion of the site located west of CR 222, the USACE representative observed approximately 100 chert flakes of mixed primary, secondary, and tertiary stages. All lithic materials appear to be of Edwards chert and are white to gray to color. Two formal tools were also observed on the surface. These include a worked uniface and a Clear Fork Uniface. In addition to the lithic artifacts observed at the site, approximately 20 FCR were observed scattered inside the ROW within and outside the immediate vicinity of the original boundary of 41NL318 (Figure 5-6).

Figure 5-6. Fragments of FCR located within the original boundary of Site 41NL318.

Diagnostic Artifact Analysis

The Clear Fork Uniface (commonly called a gouge) measures approximately 8 centimeters (3.1 inches) in length, 4 centimeters (1.6 inches) across at its distal end, and 1.5 centimeters (0.6 inches) across at its proximal end (Figure 5-7). The object is trapezoidal in cross-section measuring approximately 5 to 6 centimeters (2 to 2.4 inches) tall with a steep edge on the distal (working) end. Clear Fork Bifaces and Unifaces are prevalent through south Texas up through central north Texas. Temporally, they begin in the Paleo-Indian period and continue into the

Figure 5-7. Clear Fork Uniface (Gouge) observed on the surface at Site 41NL318.

Middle Archaic (Turner and Hester 1985 [1999 reprint] page 246-249).

Along the southern edge of the APE the USACE representative observed a previously unrecorded berm and bridge (Figure 5-8) partially inside the ROW and immediately south of the proposed ROW. The berm is oriented slightly southeast – northwest and roughly parallels the ROW along its southern edge for approximately 100 meters before continuing further away from the APE. The berm consists of local caliche gravel. The associated bridge is located approximately 3 meters (10 feet) south of the APE and is composed of a mixture of creosote timbers and roughhewn cedar planks. Portions of the supports are reinforced with sheet metal.

Preservation of the berm varied along its length, but it generally measured approximately 1.5 to 2 meters (5 to 6.5 feet) wide and 10 to 20 centimeters (4 to 8 inches) high. The berm did not appear to continue east across CR 222 and became undiscernible about 50 meters (164 feet) west of the road. Further, the berm does not appear to exist on the east side of CR 222

Figure 5-8. Section of berm that crosses the parcel and associated bridge located south of the APE.

and was only observed on the west side of the road.

Archival Research

The site is located on White Flat Road (FM 222) approximately 0.27 miles south of the road's intersection with the Gulf, Colorado & Santa Fe Railroad in Nolan County. Site 41NL318 is partially within of Abstract 311, Section 45 and Abstract 56, both in Block 19, Texas & Pacific Railway Company (T&P RY CO) Survey. Historic maps and aerials were reviewed for additional information regarding 41NL318 (Table 5-7). According to the General Land Office (GLO) records, the north half of Section 56 was originally assigned to O.E. Templin; however, no date of the transaction is available (GLO 2019a). The entire 640 acres of Section 45 was granted to the T&P Ry Co. on May 5, 1876 (GLO 2019b). GLO maps from 1880 identifies the file numbers in Section 45 as S14515 and Section 56 as F38427. No individual is shown as the owner of either section. Both sections have east-west running drainages and the site 41NL318 is located between the drainages. No buildings or activities are shown within the sections.

Table 5-7. Historical maps and aerials for 41NL318.

Type	Date	Notes
GLO Map	1880	Land assigned as Sec 45 and Sec 56 of T&P Ry Co Survey – no individual owner; east-west running drainages
GLO Map	1879	Land assigned as Sec 45 and Sec 56 of T&P Ry Co Survey – no individual owner; only Sec 56 has drainage
Sweetwater Quad Topo Map	1893	Unnamed drainage to the west; no buildings or activities within site
Soil Survey Map	1922	Gulf, Colorado & Santa Fe Railroad to the north of the site boundaries; no buildings or activities within site
Highway Map	1936	Building shown to west of White Plain Road (FM 222) in general vicinity of site
Big Spring Quad Topo Map	1954	Drainage shown to east and west of site; current configuration of roads visible; no buildings or activities within site boundaries
Merkel Quad Topo Map	1957	Road from White Flat Road through site, building to west and outside site boundaries, ponds to north and southwest; pipeline to the north and intersecting railroad
Atlas Map	1982	No buildings or structures within site
Aerial Photo	1997	Dirt road and irrigation ditch through site; building complex to west and outside site boundaries; site vegetated with trees and undeveloped to west of White Flat Road; site to east of White Flat Road is clear-cut crop or pastureland

The 1890 GLO map shows file numbers in each section with the north half of Section 56 as 49831 and the same number in Section 45, but with 2/1040 below the S14515. Only the southern drainage through Section 56 is shown, but no activities or buildings are shown in either section.

A 1922 United States Department of Agriculture (USDA) soil survey map shows Herndan as a stop on the Gulf, Colorado & Santa Fe Railroad to the northwest of the site boundaries. Toland is shown as a stop on the same railroad but is to the east of the site and within Taylor County. No activities or buildings are shown within the site boundaries. A 1936 highway map of Nolan County shows White Flat Road and a dwelling is shown between two drainages on the west side of the road, about halfway between Adrian Road (FM 130) and the east leg of White Flat Road (FM 222). A second dwelling is located on the west side of White Flat Road (FM 222) at the east leg curve of the road.

The 1954 Big Spring quad topographic map shows that the site is bisected by White Flat Road (FM 222) and that White Flat Oil Field is located to the northeast of the site. The 1957 Merkel quad topographic map shows a dirt road traveling west through the site from White Flat Road (FM 222) and leading to a structure, which is outside the site boundaries. Several small ponds and a north-south drainage are located to the north and south of the site. The pipeline is shown to the north of the site, as is the railroad. The 1982 county atlas map shows no house on the west side of White Flat Road (FM 222) in the general vicinity of site 41NL318, but the dwelling at the corner of White Flat Road (FM 222) is labeled as Lula L. Hale, Trent, 2.

The 1997 aerial shows the current configuration of the unidentified access roads to the west of the site boundaries. A faint dirt road is visible running west through the site boundaries from White Flat Road (FM 222) and an irrigation ditch is shown running northeast through the site to the ditches along White Flat Road (FM 222). The site to the east of White Flat Road (FM 222) is clear-cut agricultural crop or pastureland. The west side of the site has the dirt road and

the irrigation ditch, as well as is covered with vegetation. No buildings or structures are visible within the site boundaries. A cluster of small structures is located to the west of the site boundaries and corresponds with the location of the building shown on the 1957 quad map, which is also likely the building shown on the 1936 highway map, as the scale is often difficult to infer. In subsequent aerials, the irrigation ditch appears as a cleared corridor.

While the identified berm and bridge were initially thought to be associated with a private rail or rail spur, historic maps indicate the berm is a former private road/drive. The road appears on a 1957 topographic map and appears to pass a residence location located beyond the site boundary and APE (Figure 5-9). The road path has changed slightly since then and it is unclear when it was abandoned; however, it does not appear in the same location on a 1984 topographic map.

Historic maps and aerials reveal that no houses or buildings were located within the boundaries of 41NL318. Additionally, no historically significant events are known to have occurred at the location of site 41NL318 or in association with any persons listed on the chain of title.

Site Summary

The amounts and types of materials observed at the site suggest the site was a procurement location. The resource overall appears to have experienced moderate erosion and deflation, with only one of 9 shovel tests conducted within the site boundary/APE containing material below surface. The sparsity of subsurface deposits within the APE, few diagnostics, and shallow soils recorded during the current effort suggests the resource is not significant and is of low research value. Archival research indicates no historically significant events are known to have occurred at the location of site 41NL318 or in association with any persons listed on the chain of title. The site portion located within the APE does not retain the potential to provide significant research value and is thus recommended not eligible for the National Register, under Evaluation Criterion D.

5.2.2.2 Resources 41TA353/41TA354

Background/Previous Work

Resources 41TA353 and 41TA354 were first recorded in 2015 by Turpin and Sons, Inc. (TAS) for the Lone Star Express 24 project (Burgess and Burgess 2015). The resources were originally recorded as open camp locations of unknown prehistoric affiliations. The sites were investigated by TAS by pedestrian survey and an undocumented number of shovel tests. Both resources were discovered to be eroded and deflated with little to no soil depth. Neither of the resources were recommended for further work. Both resources were later determined to be ineligible within the pipeline ROW (THC 2019).

Site 41TA353 consisted of a lithic and FCR concentration located immediately west of Farm-to-Market (FM) 1235 along the existing pipeline ROW. The ground surface was reported to be highly eroded with widely scattered FCR in two barely recognizable concentrations suggesting displacement. Artifacts were reported to entail dozens of secondary and tertiary flakes, a probable Martindale dart point, one pointed biface, a hammerstone, an expedient tool, and a modified flake. Based on the Martindale point, site was estimated to date to the Early Archaic period.

Site 41TA354 was recorded about 160 meters west (525 feet) west of Site 41TA353, as a lithic scatter on a small deflated ridge/hill overlooking Mulberry Creek to the west. The site was reported to contain about 100 pieces of debitage, an unrecorded number of stone tools, and a remnant thermal feature indicated by the presence of FCR.

GRAY & PAPE
HERITAGE MANAGEMENT

Current Investigation

Resources 41TA353 and 41TA354 were revisited by Gray & Pape on April 10, 2019. The resource is located within Permit Area 6 to either side of FM 1235 but primarily to the west. The APE within the resources generally measures 40 meters (131 feet) wide with two areas of expanded workspace measuring approximately 47 meters (156 feet) wide (Figure 5-10 and 5-11). The location within the existing ROW is covered by short grasses but is largely exposed subsoil, rock, and cemented caliche, offering high surface visibility (Figure 5-10). The resource consists of a long, lithic scatter. Current investigation of the former resource boundaries within the corridor found that cultural materials continue between the two previously recorded resources, although somewhat sparsely as they are separated a wide low plain associated with the adjacent pond; therefore, the two boundaries have been combined. The resultant combined boundary measures approximately 450 meters (0.28 miles) east to west and 190 meters (623 feet) north to south. The landscape to the west of the site slopes sharply down from a high ridge to the adjacent waterway. The potion of the site located east of FM 1235 descends down from the road as well and is composed entirely of previous workspace with subsoil and rock visible on the surface. The resource likely extends further beyond the established boundary to the north and south but was not followed beyond that for the current project.

Initial survey of the APE recorded surface artifacts consisting of approximately 38 flakes, 7 cores, and one biface (Figure 5-12). The location of previously recorded Site 41TA354 was revisited a second time by Gray & Pape on August 7, 2019. Surface visibility was excellent, ranging from 90 to 100 percent. The location consists of a small deflated ridge that rises approximately 4.5 to 6 meters (15 to 20 feet) above the surrounding landscape (Figures 5-11 and 5-13).

Figure 5-10. Location of Site 41TA353. View is to the east.

Based on the previous site boundary the northern half of the site located within the existing ROW is gone, leaving a sharp cut bank at the northern limit of the remaining ridge. The east and west sides of the ridge are steeply sloped and largely composed of rock. An artifact scatter was observed on the surface of what remains of the ridge top. The scatter measures approximately 27 meters (88.6 feet) north-south. The artifact scatter measures approximately 16 meters (52.5 feet) at its widest point east-west but quickly narrows to a width of about 4 meters (13.12 feet) to the south.

Artifacts identified on the surface included 50+ chert debitage, 1 sandstone hammerstone (Figure 5-14 and 5-15), 1 sandstone mano (Figure 5-16), 2 multidirectional chert cores (Figure 5-13), 1 chert projectile point (Figure 5-14), 5 expedient edge-modified chert tools (Figure 5-17), 2 chert preforms (Figure 5-18), and 6+ pieces of FCR. Two attempted projectile points observed on the surface were either incomplete (Figure 5-19) or too fragmentary for cross dating. A third, however, was intact enough to yield a potential date for the site.

Figure 5-14. Sandstone hammerstone identified within the original boundary of Site 41TA354.

Figure 5-17. Multidirectional core observed on the surface within the original boundary of Site 41TA354.

Figure 5-18. Expedient/edge-modified tool observed on the surface within the original boundary of Site 41TA354.

Figure 5-19. Attempted projectile point observed on the surface within the original boundary of Site 41TA354.

Soils mapped for the location consist of Knoco-Badland complex, 1 to 12 percent slopes. Knoco soils contain a shallow surface layer of red (2.5YR 4/6) clay and reddish brown (2.5YR 5/4) clay followed by subsoil (C horizon) of reddish brown (2.5YR 5/4) dense clay and non-cemented claystone (NRCS 2019). Of the 11 shovel tests conducted within the site boundary/APE during survey none were positive for buried cultural material. Nearly all others showed signs of disturbance or erosion as indicated by the presence of subsoil and rock at the surface. A typical shovel test profile within the southern edge of the APE just outside of the existing ROW consisted of a surface layer of brown (7.5YR 4/4 to 7.5YR 4/2) sandy loam to a depth of 50 centimeters (20 inches) or less before hitting extremely hard subsoil clay or bedrock (Appendix C). Tests within the ROW recorded much less soil (typically 10 centimeters [4 inches]) prior to hitting rock. This suggests some amount of soil is present at the southern limits of the APE, but the lack of buried cultural materials suggest the site is limited to the surface.

Agency Revisit

The combined boundary of Site 41TA353/354 was revisited again by Gray & Pape along with representatives of the USACE on October 29, 2019. During a walk over of the site, the USACE representative observed a dart point on the surface at erosional water path/rill (described below). USACE observed at least 200 FCR across the larger 41TA353/41TA354 site, with concentrations in approximately three areas and a steady FCR scatter across the general site area. FCR concentrations include one discreet feature (Feature 1 described below) and two additional diffuse FCR scatters, outside the original 41TA353 or 41TA354 site boundaries, but within the larger revised 41TA353/41TA354 site boundary near an existing stock pond. One of these scatters consisted of approximately 12 large (15-20 centimeter [5 to 8-diameter]) FCR that may represent a single use hearth feature based on the lack of fracturing. USACE also observed one formal biface fragment and one formal uniface fragment inside 41TA353 on the surface. 100-200 flakes, 2 cores, and 4 expedient tools were also observed across site 41TA353/41TA353.

In total the site contains over 230+ lithics and 200+ FCR (Table 5-8). Flakes represented all stages of processing but primarily of early to mid-stages as most were large and contained cortex. All material was of local (likely Edwards) chert and nearly all exhibited a gray color. Two diagnostics identified at the site are discussed in more detail below.

Table 5-8. Artifact Assemblage Observed at 41TA353/354.

Depth	Flakes	Bifaces	Uniface	Cores	Hammerstone	Mano	Tools	Projectile Point	Preforms	FCR
Surface	200+	2	1	12	1	2	9	2	2	200+
0-10	1	-		-	-	-	-	-	-	-
10-20	-	-		-	-	-	-	-	-	-
20-30	-	-		-	-	-	-	-	-	-
30-40	-	-		-	-	-	-	-	-	-
40-50	-	-		-	-	-	-	-	-	-

Diagnostic Artifact Analysis

A total of two diagnostic artifacts were observed within the expanded site boundary:

The first is a small, stubby projectile point (Figure 5-20) with a triangular blade and random flaking pattern was located on the surface of the deflated ridge among the scatter of debitage, cores and other stone tools in the previously recorded boundary of Site 41TA354 (Figure 5-20).

Figure 5-20. Elam dart point observed on the surface within the original boundary of Site 41TA354.

It has a maximum length of 29 millimeters (1.14 inches) with evidence of heavy resharpening at the distal end. Although the barbs have been damaged, the maximum width across the shoulders measures 24 millimeters (0.94 inches). The stem is slightly contracting and measures 9 millimeters (0.35 inches) in length and 14 millimeters (0.55 inches) in width. Based on these attributes, the point most likely represents an Elam dart point. These have a distribution primarily in North central Texas into east Texas and are dated to the Late Archaic Period (Turner, Hester, and McReynolds 2011).

The second diagnostic observed at the site consists of a small to medium sized (approximately 4-centimeter [1.5-inch]) broad triangular dart point (Figure 5-21) identified on or adjacent to an erosional flowline/rill leading into the existing pipeline ROW.

Figure 5-21. Modified Carrollton or Edgewood type dart point observed on the surface within the original boundary of Site 41TA353.

The point is composed of gray/black waxy (possibly due to heat treatment) chert with fossil inclusions. It has a maximum length of 37.5 millimeters (1.47 inches). The maximum width across the shoulder/body measures 25 millimeters (0.98 inches). The stem is slightly contracting and measures 10 millimeters (0.39 inches) in length and 10 millimeters (0.39 inches) in width. The body has a plano-convex cross section and the stem is slightly contracting.

This point appears to be reworked, missing portions of base and shoulders, but based on general size, flaking, and shape this could be a type dart such as shows affinity with Carrollton or possibly Edgewood dart points dating to the middle archaic to transitional archaic (Turner and Hester1985 [1999 reprint] page 85).

Supplemental Investigation of Feature 1

One concentrated and discreet thermal feature was observed inside the original boundary of site 41TA353. Feature 1 contained approximately 50 FCR in a 1-meter (3.3-foot) diameter concentration within the existing ROW (Figure 5-22). The concentration included a groundstone mano that has been fire cracked. The feature is located within the existing ROW and may represent one of the features mentioned in the original site record. At the request of the USACE, Gray & Pape revisited the site on November 5, 2019 to further investigate the feature in an attempt to discern if any subsurface portion of the feature remains intact.

Figure 5-22. Feature 1: discreet FCR scatter within the existing ROW and previously recorded site limits of 41TA353. View is to the southeast.

Two shovel tests were excavated within the feature and five others were placed around the feature at 5 to 10-meter (16 to 33-foot) intervals (Figure 5-23). Only one test (F1-1), performed at the center of the feature, contained subsurface material: one primary flake located just below the surface. The remaining tests were negative for any cultural materials or deposits suggestive of a thermal feature. Shovel Test F1-1 contained a profile of 2.5YR 5/8 clay and stone with a slight amount of what likely consists of windblown silt at the surface. Soils in and around the feature as indicated by Test F1-1 were very shallow and barely penetrable, reaching at most 20 centimeters (8 inches) through hard clay and rock (Appendix C).

Site Summary

The location has been previously disturbed by pipeline installation, and erosion/displacement. While a deflated feature was identified within the existing ROW, shovel testing in and around the feature produced no intact subsurface evidence of thermal activity. Rather, tests displayed a shallow, disturbed, or deflated soil and artifacts appear to be limited to the surface within the location. Of the total of 18 shovel tests conducted within the resource boundary/APE, only one contained cultural materials: a single flake just below surface. Although Feature 1 and two other clusters of FCR display some amount of spatial integrity, the lack of subsurface deposits within the APE and signs of disturbance observed during the current effort suggests the resource overall is not significant within the ROW. The site portion located within the APE does not retain the potential to provide significant research value, such as radiocarbon dating, and is thus recommended not eligible for the National Register, under Evaluation Criterion D.

5.2.2.3Site 41TA314

Background/Previous Work

41TA314 was originally recorded by Horizon in 2013 for the BridgeTex Pipeline ROW survey (Brownlow et al. 2014). The resource consists of a low-density surficial lithic scatter of unknown prehistoric affiliation. The site sits along a gentle slope directly west of Bull Wagon Creek. Horizon investigated the site within the Project ROW by pedestrian survey and six shovel tests. The observed artifact assemblage consisted of two retouched flakes, one secondary flake, and two tertiary flakes, all comprised of chert. No temporally diagnostic formal tools preserved floral or faunal remains, or thermally altered rocks, were noted on the site. All six shovel tests were negative for cultural materials or features. Horizon did not investigate the entire site boundary beyond the ROW; however, based on the lack of temporally diagnostic stone tools, any preserved floral or faunal remains, or stratified, buried cultural deposits within the ROW, Horizon recommended that the portion of site located within the ROW would not contribute to the site's overall NRHP eligibility status. The resource was not recommended for further work and was later determined to be ineligible within the pipeline ROW (THC 2019).

The resource was revisited by TAS in 2015 for the Lone Star Express 24 survey (Burgess and Burgess 2015). As a result, the site size was roughly doubled and expanded to the south-southwest. TAS investigated the site by pedestrian survey and the excavation of six shovel tests within the Project ROW and corresponding expanded site boundary. Observed surface cultural material included a few scattered FCR but no intact thermal features, and about 50 lithics including: a Marcos dart point, utilized flakes, as well as secondary and tertiary flakes. Of the six excavated shovel tests, only one was positive, containing a single flake between 0 and 10 centimeters (0 and 4 inches) below ground surface. Based on the identified Marcos dart point, the resource was considered to be of Late to Transitional Archaic temporal affiliation. The area has been disturbed by bioturbation and existing pipelines. Two brush piles observed by TAS at the time also suggested brush clearing. As a result of survey, TAS determined the site to be deflated. No further investigations were recommended due to the low potential for subsurface deposits.

Current Investigation

Resource 41TA314 was revisited by Gray & Pape on April 10, 2019. The resource is located within Permit Area 9. The APE at the location predominantly measures 40 meters (131 feet) wide with one area of expanded workspace extending to 55 meters (180 feet) (Figure 5-24). The location within the existing ROW is covered by short grasses offering good surface visibility which decreases significantly beyond the ROW to the south (Figure 5-25). The location appears to be primarily used for cattle grazing. The resource consists of a sparse surficial lithic scatter. Surface artifacts observed during the initial survey consist of approximately 20 flakes and one chert core (Table 5-9). These were all located within the expanded site boundary recorded by TAS in 2015, which is now entirely within the existing pipeline ROW (Figure 26). Investigation in April 2019 consisted of pedestrian walkover and nine shovel tests excavated at 30 to 50-meter (100 to 164-foot) intervals: three tests within the site boundary and six tests within the surrounding APE (Figure 5-24).

Soils mapped for the location consist of Tillman clay loam which consist of surface layers of brown (7.5YR 5/3 to 4/3) loam and clay loam (NRCS 2019). A representative shovel test profile placed outside of the existing ROW consisted of brown (7.5YR 4/4) sandy loam to a depth of 25 centimeters (10 inches) followed by compact brown (7.5YR 4/4) clay to a depth of 35 centimeters (14 inches) before hitting extremely hard subsoil clay or bedrock. This profile closely matches soils mapped for the location.

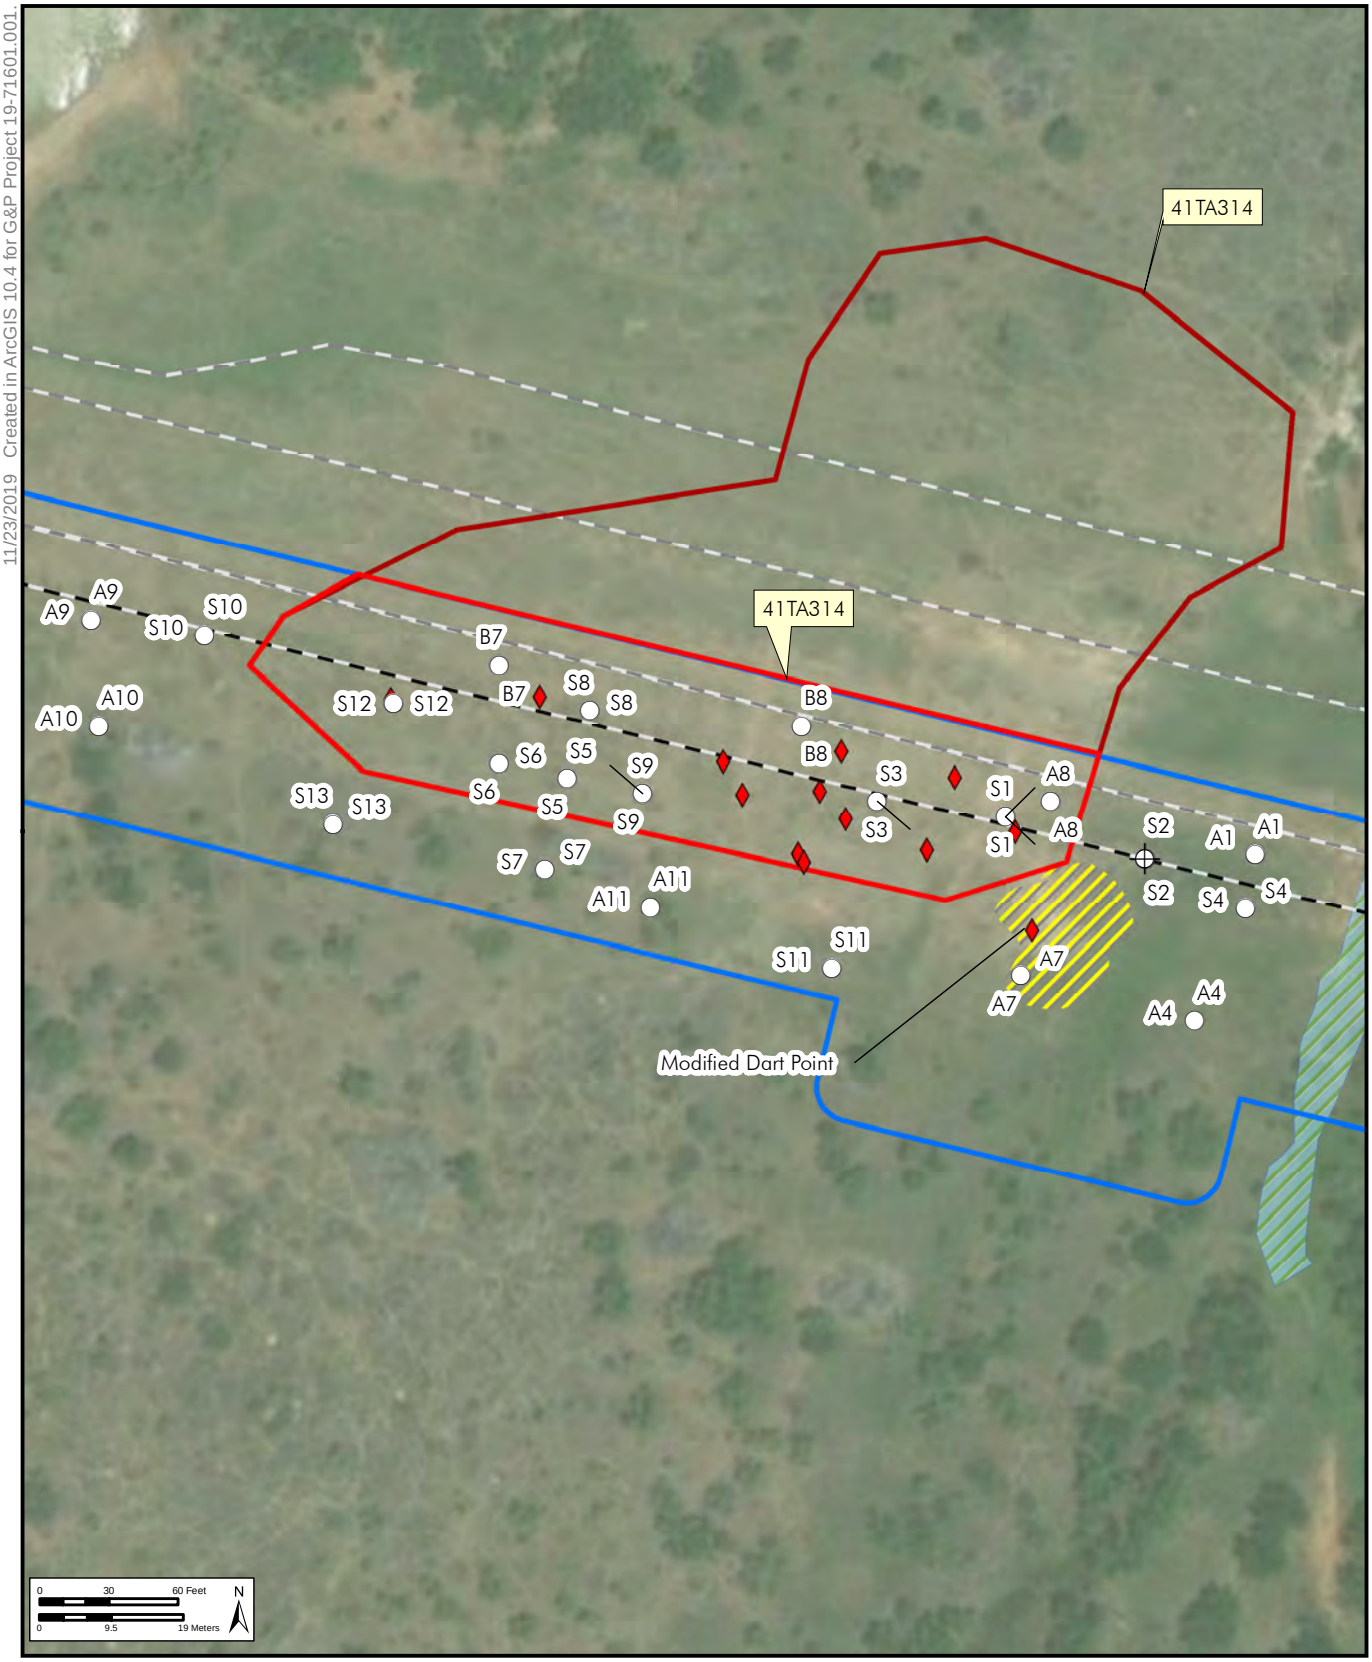

Figure 5-24

However, within the existing ROW soils were typically much shallower, composed of very compact silty clay, and containing numerous rock fragments and gravels. This was particularly the case in the western portion of the site/APE which is at a higher elevation on the hillside and appears to have experienced more erosion.

20-30	-	-	
30-40	-	-	

Figure 5-26. Representative materials identified on the surface within Resource 41TA314.

Supplemental Investigation

A supplemental survey of the site by Gray & Pape took place on November 5, 2019. During the revisit, approximately 14 primary or secondary stage flakes were observed as well as two cores and two worked unifaces. Photographs from the previous survey confirm that several of the artifacts were identified during the site visit in April. One new, potentially diagnostic dart point was observed on the surface during the November revisit. This is discussed further below. All artifacts were composed of a local (likely Edwards) chert of waxy gray to grainy white chert. As well as lithics, about a dozen FCR were also observed spread within the existing ROW but not in any discernable clusters or association with cultural lithics.

Supplemental work in November 2019 resulted in the excavation of an additional 13 shovel tests: six tests within the site boundary and seven within the surrounding APE. One of these tests was in the immediate vicinity of the damaged projectile point. Of all 22 tests placed in and surrounding the site, only one was positive for cultural materials. Shovel Test S2, located at the bottom of the adjacent slope, contained a single primary or secondary flake between the surface and 5 centimeters (2 inches) depth.

Diagnostic Artifact Analysis

One damaged medium sized corner-notched dart point was observed on the surface of an eroded slope southeast of the previously recorded site boundary (Figure 5-27). The distal end is broken, and one side is heavily damaged at the shoulder with evidence of reworking. The stem is slightly expanding and parallels the blade edge. The tip of the barb is also damaged. Extrapolation of the barb indicates a rather deep notch. It has a maximum length of 47 millimeters (1.85 inches). Although the barbs have been damaged, the maximum width across the shoulders measures 35 millimeters (1.38 inches). The stem (also modified) measures 8 millimeters (0.31 inches) in length and 15 millimeters (0.59 inches) in width.

Damage and modification of this point curtails a clear diagnostic typing. But the deep barb and slightly expanding stem shows affinity to Marshall dart points. Marshall points date to the middle Archaic and are found primarily in central Texas (Turner and Hester 1985 [1999 reprint] page 149-150).

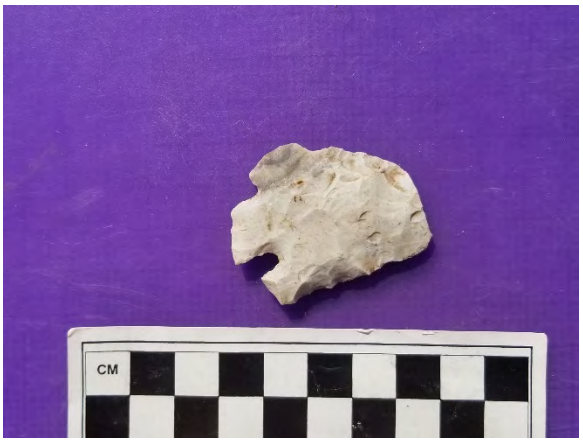

Figure 5-27. Damaged/modified dart point (possible Marshall) observed on an eroded slope southeast of Site 41TA314.

Site Summary

The resource likely extends to the north as indicated by the previously recorded site boundary; however, this portion of the site was not re-examined during the current survey effort. The portion of the site located within the APE is largely limited to the existing pipeline corridor and is clearly disturbed. Although what appear to be natural soil profiles were observed within the APE beyond the existing pipeline ROW, tests placed in these areas produced no subsurface cultural materials or features. Of the ten shovel tests conducted within the site boundary/APE only one was positive: a single flake within colluvial material at the base of the slope. The overall lack of subsurface deposits within the APE, lack of diagnostics in good context, and signs of disturbance observed during the current effort suggests the resource is not significant within the current APE. No further work is recommended for the site. The site portion located within the APE does not retain the potential to provide significant research value and is thus recommended not eligible for the National Register, under Evaluation Criterion D.

5.2.2.4 Resource 41CA27

Background/Previous Work

Resources 41CA27 was first recorded in 2015 by TAS for the Lone Star Express 24 project (Burgess and Burgess 2015). The resource was originally recorded as a small open camp location of unknown prehistoric affiliations. The site is located on a terrace alongside Mexia Creek approximately 100 meters (328 feet) west of Highway 283. The site was reported to consist of surface finds of two FCR concentrations and approximately 15 mostly tertiary flakes, one of which was of chalcedony. No intact features or more formal artifacts were identified at the site. The site was reported to have been damaged by erosion and adjacent pipeline construction as well as a two-track road which passes through the site. The site was not considered to be eligible for listing on the NRHP. In 2015, the THC determined the site to be ineligible (THC 2019).

Current Investigation

The location of Site 41CA27 was revisited by Gray & Pape on April 11, 2019. The location intersects the APE at Permit Area 40. The APE at the location measures 55 meters (180 feet) wide, with approximately 45 meters (148 feet) of that width located within an existing pipeline ROW (Figure 5-28). The northern edge of the APE, and a portion of the previously recorded site boundary, consists of a wide gully and slope, likely the result of flooding from an adjacent fork of Mexia Creek and subsequent erosion or truncation of the landscape as a result of previous pipeline installation. The existing ROW south of the gully is nearly level but also appears disturbed, with a great deal of rock and short grasses on the surface which allowed good surface visibility (Figure 5-29). Surface visibility is decreased beyond the ROW which is covered by longer grasses and scrub brush. Besides having been impacted by the existing pipelines, access roads and also cut through the mapped site location.

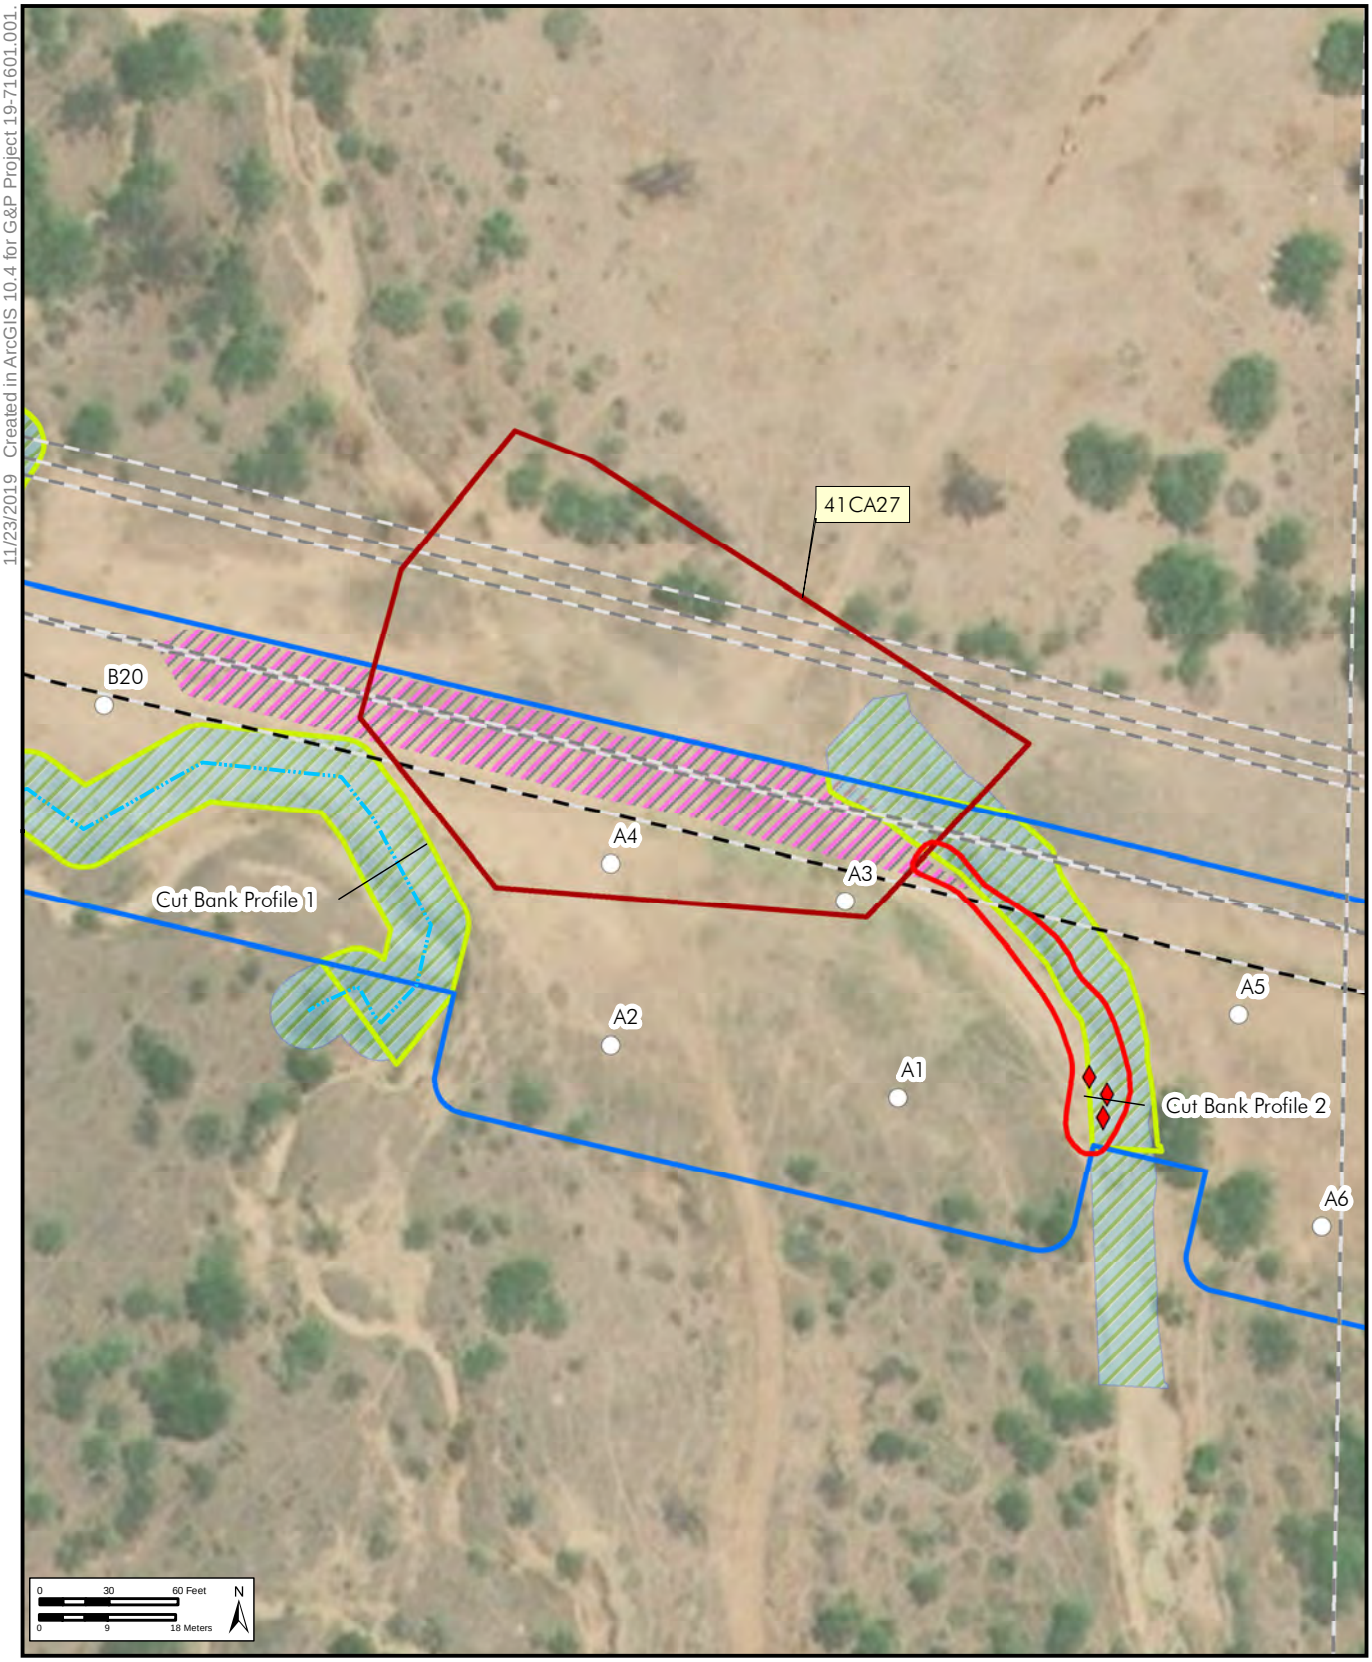

Figure 5-28
Plan view of Resource 41CA27.

GRAY & PAPE

- Low Area

Figure 5-29. Location of Site 41CA27 showing the east fork of Mexia Creek (background) and portion of the low/eroded north side of the APE (center left). View is to the east.

Investigation of the resource consisted of pedestrian walkover and shovel testing. Gray & Pape observed no cultural materials on the surface during survey. Two shovel tests were placed within the mapped site location, both were negative for cultural materials but did show signs of disturbance. Another four tests were conducted within the ROW south of the site, all of which were negative for cultural materials.

Soils mapped for the location consist of Frio-Gageby association, frequently flooded. Frio soils consists of successive A horizon layers of dark grayish brown (10YR 4/2) silty clay, clay loam, and silty clay loam to a depth of 102 centimeters (40 inches) followed by a B horizon of grayish brown (10YR 5/2) silty clay to a depth of 203 centimeters (80 inches) (NRCS 2019). Gageby soils consist of a surface layer (A horizon) of brown (7.5YR 4/2) clay loam to a depth of 18 centimeters (7 inches). That is followed by a subsurface (A2 horizon) of brown (7.5YR 4/2) sandy clay loam to a depth of 61 centimeters (24 inches). Below that is successive B horizons of yellowish red (5YR 5/6) sandy clay loam to a depth of 203 centimeters (80 inches).

Shovel tests placed within the mapped site boundary consist of mottled brown (7.5YR 4/4) and yellowish red (5YR 5/6) sandy clay loam to a depth of 5 to 10 centimeters (2 to 4 inches) before the density of the soil and rock became impenetrable (Appendix C). This profile suggests soils within the site boundary are deflated and or truncated. Shovel tests located at the southern margins of the existing ROW to the south contained thicker soil deposition, containing a profile of brown (7.5YR 4/4) sandy loam to a depth of 50 centimeters (20 inches) followed by hardpan silty clay and bed rock.

Agency Revisit

The site was revisited by Gray & Pape and representatives of the USACE on October 29, 2019. During a walk over, the USACE representative observed approximately 12 FCR in the existing ROW. In addition, one modified flake, one bifacial edge failure flake (Figure 5-30, Table 5-10)), and one mussel shell fragment were identified within the APE but outside the recorded site boundary along a stream profile east of the known 41CA27 boundary (Figure 5-28). Both flakes were composed of local (likely Edwards) chert and were of gray coloration. Based on these finds, the site boundary has been expanded to the east along the edge of the waterway. The original recorders of 41CA27 observed FCR features and based on USACE's observations these features were likely north of the proposed ROW. USACE observed FCR scattered along the surface north of the proposed ROW that may represent FCR features impacted by previous pipelines.

Figure 5-30. Bifacial edge failure flake observed on the surface of the cut bank at Site 41CA27.

Table 5-10. Artifact Assemblage Observed at 41CA27.

Depth	Flakes	FCR	Mussel Shell
Surface	2	12	1
0-10	-	-	-
10-20	-	-	-
20-30	-	-	-
30-40	-	-	-

Supplemental Investigation

As stated above, waterways to either side (west and east) of the previously recorded site boundary were inspected for any cultural materials or buried features (Figure 5-28). A profile for each waterway was recorded to supply additional information on the soils present in the location.

Cut Bank Profile 1 – West Waterway

The west waterway was dry at the time of the visit and although it contained a good deal of vegetation along its bank, visibility was good overall (Figure 5-31). A profile of the bank, taken from the east bank, consists of uniform compact 7.5YR 6/4 silty clay loam (Figure 5-32). This profile continued from the surface all the way to the bottom of the cut, which was approximately 2 meters (6.6 feet). In places where the bank was sharply cut, small sized rock was observed protruding at all levels and especially at the base of the profile. No cultural materials, buried surfaces, features, or potential cultural horizons were observed within the cutbank either at the profile or anywhere along the cut bank within the APE.

Figure 5-31. West fork of Mexia Creek located just west of the previously recorded boundary of Site 41CA27. View is to the east.

Figure 5-32. Cut Bank Profile 1 located in the western fork of Mexia Creek. Profile is located in the east cut bank. View is to the northeast.

Cut Bank Profile 2 – East Waterway

The east waterway was likewise dry at the time of the visit, containing less vegetation as the banks are more eroded along its bank than to the west. Visibility was very good overall (Figure 5-33). A profile of the bank, taken from the west bank, consists of uniform 7.5YR 6/4 compact silty clay loam. Several small to medium rocks are observed protruding at all levels down to the base of the cut where rock becomes large and increasingly dense. The base of the cut is approximately 2 meters (6.6 feet) at the deepest. One small mussel shell fragment was observed in the profile approximately 35 centimeters (13.78 inches) below surface. As stated above, a one modified flake, one bifacial edge failure flake was also observed nearby in this area. Other than these few artifacts, no cultural materials, buried surfaces, features, or potential cultural horizons were observed within the cutbank either at the profile or anywhere along the cut bank within the APE.

Figure 5-33. Cut Bank Profile 2 located in the eastern fork of Mexia Creek. Profile is located in the west bank. Note mussel shell in center of picture. View is to the west.

Site Summary

The small portion of previously recorded site located within the APE appears to have been impacted by previous pipelines and erosion as evidenced by a low washed out area and truncated adjacent landscape. The area inside the APE south of the site is relatively small and likewise impacted. Inspection of the surface within the previously recorded site boundary within the APE produced no cultural materials aside from a few scattered FCR within the low pipeline corridor and adjacent slope. Shovel tests conducted within and outside the site boundary produced no cultural materials. Inspection of the cut banks of two forks of Mexia Creek produced only a few artifacts out of context. Soil deposits suggest deflated or truncated soils within the existing ROW due to previous pipeline installations. Soils observed in the cut bank showed no evidence of buried surfaces or cultural horizons. The bulk of the resource is likely to the north of the APE as observed during the revisit by the USACE. Any portions of the site located along the previously installed pipelines are likely destroyed. No further work is recommended for the location. No attempt was made to investigate outside of the APE to the north during the current effort.

5.2.3 Newly Identified Resources within Jurisdictional Areas

Six new resources were identified as a result of survey within jurisdictional permit areas in Loop 2. These are described below in order of appearance on the alignment from west to east.

5.2.3.1 Resource 41TA396

Resource 41TA396 was identified by Horizon on April 10, 2019. The resource consists of a mid-twentieth century trash dump and sparse prehistoric lithic scatter. The resource is located in Permit Area 3, approximately 0.5 kilometers (0.3 miles) north of CR 386 and 0.9 kilometers (0.6 miles) west of CR 349. The location is on a moderate slope between an upper and lower terrace roughly 65 meters (213 feet) east of a wetland and around the northern perimeter of a

man-made pond. The site is nearly entirely located within the existing pipeline corridor covered by short grasses offering good surface visibility (Figure 5-34). The landscape drops off significantly to the south of the existing ROW (Figure 5-35). The APE at the location measures 40 meters (131 feet) wide, with approximately 30 meters (100 feet) of that distance within an existing pipeline ROW. The resource boundary within the corridor measures approximately 50 meters (164 feet) east-west by 40 meters (131 feet) north-south. The location also appears to be bisected by a two-track road.

Figure 5-34. Location of Site 41TA396. View is to the southeast.

Investigation of the APE consisted of pedestrian survey and the excavation of shovel tests spaced between 15 and 20 meters (49 and 66 feet) (Figure 5-35). Historic materials observed on the surface within the resource include at least five ceramic fragments, 10 glass shards (Figure 5-36), 10 brick fragments, and 10+ metal and construction debris. Observed prehistoric materials include at least ten flakes of mostly mid to late stage, one biface, and one projectile point (Table 5-11, Figure 5-37). A total of six shovel tests were conducted at the location: five within and one beyond the west edge of the site boundary.

Supplemental Investigation

A supplemental visit of the site by Gray & Pape took place on November 5, 2019 to further delineate the site and collect diagnostic information of the historic artifacts. Gray & Pape observed approximately 150+ glass fragments representative of multiple vessels, a more limited number of ceramic fragments (25+), 1 brick fragment and approximately 10 metal fragments. In addition to the historic artifacts, approximately 12 flakes were observed. These consisted of secondary and tertiary stage and were all composed of local (Edwards or similar material) chert of gray or tan coloration. Three additional shovel tests were conducted within at the location: two within and one beyond the east edge of the site boundary. Further, areas of project corridor to the east and west of the site were graded at the time of supplemental work. Grading penetrated approximately 15 to 20 centimeters (6 to 8 inches) below surface (Figure 5-38). These areas were inspected for additional materials or features. None were observed.

Table 5-11. Artifact Assemblage Observed at 41TA396.

Figure 5-37. Representative prehistoric materials identified on the surface within Resource 41TA396.

Figure 5-38. Graded section of pipeline workspace located east of Site 41TA396. View is to the south.

Between the two site visits, a total of nine shovel tests were excavated at the location: eight within the site and one beyond the west edge of the boundary. Soils mapped for the location include Clairemont silty clay loam and Pitzer-Weymouth complex (NRCS 2019). A typical shovel profile within the resource consisted of red (2.5YR 4/6) clay subsoil to a depth of 40 centimeters (16 inches) (Appendix C). This profile was confirmed by what was observed in the graded sections of pipeline workspace located beyond the site. The soil was extremely compact at the location and contained numerous calcium carbonate concretions. Of eight shovel tests conducted within the scatter, only one was positive for buried cultural material. This test produced a single chert flake between 0 and 10 centimeters (4 inches) below the ground surface. This test is located at the bottom of the slope and is likely colluvial. The resource does not likely continue beyond the ROW to the north and south due to existing disturbances, however, a corral located approximately 50 meters (164 feet) north of the ROW may be a source for some of the construction debris.

Diagnostic Artifact Analysis

Historic artifacts date to the mid to late twentieth century as evidenced by color, seams, finish, and makers marks. Among the assemblage are artifacts that include aqua, green, clear, cobalt, opaque white, and brown colored glass (Figure 5-36), ferrous metal and can fragments and ceramics that include a few fragments of whiteware, or ironstone, hand painted whiteware, and porcelain. Overall, the majority of the artifacts largely post-date 1915 and extend to into the mid-twentieth century. Specific diagnostic examples include a fluted or paneled colorless possible twentieth century soda bottle; likely cosmetic jar with a continuous threaded finish (usually machine-made and 20th century); standardized machine-made glass jar with thread finish (after 1930s per Deiss 1981:95; Leif 1965:29) (Figure 5-40), machine-made bottle with a crown finish (after 1915) (Figure 5-41).

Figure 5-39. Clear glass jar with continuous thread finish.

Figure 5-40. Crown finish on beverage bottle.

The lone prehistoric diagnostic artifact consists of a projectile point with the following characteristics. It measures 39 millimeters (1.5 inches) long overall (after resharpening). It consists of a triangular to ovoid blade, with a random flaking pattern. The barbs span a total of 35 millimeters (1.38 inches) with one barb longer than the other and appears to have been re-sharpened with recurvate edges. The stem is slightly expanding, measuring 12 millimeters (0.47 inches) long by 21 millimeters (0.83 inches) wide. The base of the stem appears to be thinned and ground with a slightly convex edge. Based on these attributes, the point mostly likely represents a Marshall dart point. These have a distribution primarily in central Texas, contemporary with Pedernales, dated to the Late Middle Archaic (Turner, Hester, and McReynolds 2011).

Figure 5-41. Probable Marshall dart point identified on the surface within resource 41TA396.

Archival Research

Archival research of the property was undertaken to further investigate the historic component of the resource. A limited title search was conducted by Lone Star NGL Pipeline LP by the Taylor County Clerk's Office (Table 5-12). The property is located at 2843 FM 1085 in Taylor County. The current parcel (Property ID 69643) is part of Abstract A-375 and contains 397 acres in Section 61, Block 19, Texas & Pacific Railway Company (T&P RY CO) Survey. The current owner, Janet A Whisenhunt also owns the 160-acre parcel to the north in Abstract A-1251, Section 52, Block 19 of the T&P RY CO Survey. Transactions prior to 1980

Table 5-12. Deed Research Results for 41TA396.

Grantee	Grantor	Grantor Sell Date	Description Type; Deed Volume/Page	Additional Information
Sunoco Pipeline, LP	Dink and Jan Whisenhunt	3/10/2014	Permanent Easement Agreement	397 acres Sec. 61, BLK 19, T&P Ry Co Survey, A-375; 40 ft for one pipeline

were not located by the County Clerk's Office or online. Historical maps and aerials were reviewed for additional information. According to the General Land Office (GLO) records, Abstract 375 was surveyed by the T&P Ry Co and assigned on August 27, 1874 (GLO 2019). A 1934 atlas of Taylor County identifies Section 61 of Block 19 of the T&P RR lands as unassigned. A 1940 map shows that the section was split into five different parcels. The boundaries for site 41TA396 are located within the western half, which was divided into two parcels, the northwest labeled Humble and the southwest labeled as --J Adcock, Merkel. The first initial of the owner is obscured by the Gulf, Colorado, and Santa Fe Railroad symbol. The Adcock family was rather large and consisted of several individuals with J as a middle initial. Ransom Jefferson Adcock was born on May 18, 1846 in Holly Springs, Mississippi and moved to Texas by 1880, where he was listed on the census in Navarro as a farmer (Ancestry 2019a, Find-a-Grave 2019a). He was married to Dorinda Anne Brown, who died in 1907 in Merkel, Texas. They had only one child, a daughter named Belle. However, Ransom had approximately six siblings, and at least one of them, Robert Alexander Adcock, also moved to Texas, but he lived in Gustine, Comanche County, Texas. Robert was married twice to Martha Ellen Brown Adcock (1855-1889) and to Elizabeth Louise Roberts Adcock (1871-1912) (Find-a-Grave 2019b). Robert had four children with his first wife, including son, Oscar Johnson Adcock (1880-1967), and eight with his second wife, including Ransom Jefferson Adcock (1898-1979). Ransom was born and died in Gustine, Comanche County, Texas; however, Oscar, while born in Navarro, Texas, died in Merkel in 1967. Oscar married Cora Lee Bankhead Adcock and has four children, including Oscar Johnson, Jr on April 21, 1916 in Merkel, Texas (Find-a-Grave 2019c). Oscar, Jr. married his wife, Loraine J. McGaughy Adcock, in 1938 and they moved to Fort Worth (Find-a-Grave 2019d). Oscar, Sr. was listed on

the 1910 census as a rural route mail clerk in Merkel and on the 1930 census as the postmaster of the Merkel Post Office (Ancestry 2019b, 2019c). Based on his age and residence, it is most likely that Oscar, Sr. was the owner of the Section 61 southwest corner in 1940. The exact transaction date and which Adcock purchased the southwest portion of Section 61 is unknown at this time. Historic maps and aerials reveal that no houses or buildings were located within the boundaries of 41TA396 (Table 5-13).

A chain of ownership extending back to 1980 was provided by Lone Star NGL Pipeline LP for the property on which site 41TA396 is located (Appendix D). According to the deeds, William Arch Daniel was the earliest known owner and his estate was sold by the First National Back of Abilene in 1980. William Arch Daniel, known as Arch, was born in Wood County on January 31, 1891. He was a rancher, farmer, and business owner who operated Daniel Wholesale Auto Parts in Abilene. Arch served in World War I and married to Nina Pearl Morrison on September 24, 1924. He was also a member of the First Baptist Church since 1928, Masonic Lodge No. 195 RAM, Knights Templar Council No. 10, a member of the Farm Bureau, and patron of the Order of Eastern Star, Cora Posey Chapter No. 1072 (Find-a-Grave 2019e).

Additional deeds were not found for this property during the search and a search of online records yielded the same result. A search of the Handbook of Texas Online for the names of past landowners reveals that no persons of historical significance are associated with this site. Additionally, no historically significant events are known to have occurred at the location of site 41TA396 or in association with any persons listed on the chain of title.

Site Summary

Aside from one flake discovered in what is likely a colluvial context, all of the identified materials were identified on the surface. The resource appears to have experienced heavy disturbance and deflation due to previous impacts, including the existing pipeline corridor, two-track road, and man-made pond. The location appears to be a dumping ground for historic and modern material associated with the adjacent ranchland and agricultural fields.

Table 5-13. Historical maps and aerials for 41TA396.

Type	Date	Notes
GLO Map	1859	Land unassigned – not shown on GLO map
GLO Map	1879	T&P RR, Block 19, Sec 61 unassigned to an individual but shown on map
GLO Map	1883	T&P RR, Block 19, Sec 61 unassigned to an individual but shown on map – "S. 14523 ptd" labeled within Sec. 61
Sweetwater Quad Topo Map	1893	Drainage to the north of the site; no buildings within or adjacent to site
Soil Survey Map	1922	Site located between T&P RR through Merkel to north and Gulf, Colorado, and Santa Fe Railroad to south – not within site boundaries
Atlas Map	1934	T&P RR, Block 19, Sec 61 unassigned to an individual but shown on map
Atlas Map	1940	Sec. 61, Block 19 split into 5 parcels; NW quarter – Humble, 7-5-33; NE – FC unknown, 1-5-31; NE – Hurley; SW – --J Adcock, Merkel; SE – C. Cormes, Merkel
Merkel Quad Topo Map	1957	FM 1085 and 386 visible, pipeline shown through site, pond to south; no buildings within or adjacent to site boundaries
Atlas Map	1972	no buildings shown within or adjacent to site boundaries; bridge on FM 1085 to west of site
Atlas Map	1982	no buildings shown within or adjacent to site boundaries; bridge on FM 1085 to west of site
Aerial Photo	1996	No buildings or structures; pond visible to the south of the site; cultivated cropland with plow marks to northeast and southwest; site is vegetated with possible cleared area or road in northeast corner of site boundaries

The prehistoric materials likewise are most likely out of context. Other than the lone projectile point found at the location, the relatively recent date and commonality of the historic materials, shallow soils, lack of features, and lack of associated historically significant persons or events identified during the current effort suggests the resource within the ROW is not significant. No further work is recommended for the location. The site portion located within the APE does not retain the potential to provide significant research value and is thus recommended not eligible for the National Register, under Evaluation Criterion D.

5.2.3.2 Resource 41TA397

Resource 41TA397 was identified by Horizon on April 15, 2019. The resource consists of a historic to modern trash dump and sparse surficial artifact scatter of mid-twentieth century domestic debris. The resource is located in Permit Area 5, approximately 7 meters (23 feet) north of CR 393 and 250 meters (831 feet) east of CR 126, west of a drainage associated with a man-made pond/catch basin (Figure 5-42 and Figure 5-42). The APE at the location measures between 24 to 55 meters (79 to 180 feet). The location at the time consisted of a slightly fallow wheat field so surface visibility was 100 percent (Figure 5-44). Observed surface materials include a sparse (50 or less) number clear bottle glass (including neck), brown glass, milk glass, whiteware ceramic, and unidentifiable metal fragments.

The scatter of items is lightly concentrated in the southern portion of the site near the road with fewer and fewer artifacts observed moving outward from there until they become outliers. No intact structures such as foundations were identified. The resource boundary within the APE measures approximately 85 meters (278.87 feet) east-west by 50 meters (164.04 feet) north-south. Six shovel tests were conducted within the densest area of the scatter, of which only one was positive for buried cultural material, consisting of a single whiteware fragment discovered in the top 10 centimeters (4 inches) below surface within the plow zone.

Supplemental Investigation

A supplemental visit of the site by Gray & Pape took place on November 5, 2019 to collect diagnostic information of the historic artifacts.

Figure 5-42. Conditions at Site 41TA397 in April 2019. View is to the east.

The materials present were very sparse and amounted to approximately a dozen glass fragments representative of multiple vessels, 10+ ceramic fragments, 1 ceramic tile fragment, and one metal harness buckle or industrial chain link (Figure (5-44) were observed on the surface (Table 5-14). Areas of project workspace located to the northwest of the site were graded at the time of supplemental work. Grading penetrated approximately 15 to 20 centimeters (6 to 8 inches) below surface. This area was inspected for additional materials or features. None were observed.

Soils mapped for the location consist of Sagerton clay loam and Rotan clay loam (NRCS 2019). A typical shovel test profile within the resource/APE consisted of a surface layer of yellowish red (5YR 4/6) silt to a depth of 10 centimeters (3.94 inches) followed by reddish brown (5YR 4/4) cemented subsoil clay to a depth of 25 centimeters (10 inches) (Appendix C). This profile suggests the soils may be truncated or deflated.

30-40	-	-	-
40-50	-	-	-

Diagnostic Artifact Analysis

Historic artifacts observed at Site 41TA397 date to the mid to late 20th century as evidenced by color, seams, finish, and makers marks. Among the assemblage are artifacts that include clear and opaque white, and brown colored glass. Ceramics include a few fragments of whiteware, or ironstone, and one stoneware fragment. Overall, the majority of the artifacts largely post-date 1915 and extend to into the mid-twentieth century. Specific diagnostic examples include an embossed Hazel-Atlas maker's mark (1920-1964) (Figure 5-45) (Toulouse 1971: pg239) and a fragment of stoneware exhibiting a Bristol glaze (1920+) (Figure 5-46) (Greer 1999).

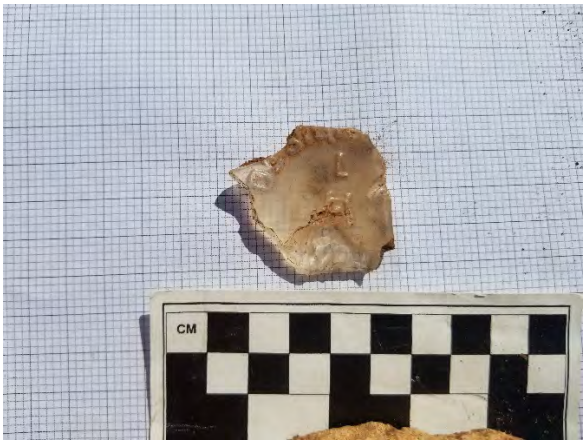

Figure 5-45. Glass bottle base with Hazel-Atlas maker's mark.

Figure 5-46. Stoneware with Bristol glaze.

Archival Research

Archival research of the property was undertaken. A limited title search was conducted by Lone Star NGL Pipeline LP by the Taylor County Clerk's Office. The property is located on FM 126 in Taylor County (Table 5-15). The current parcel (Property ID 28857) is part of Abstract A-751 and contains 160 acres (more or less) in the NW quarter of Section 6, Block 18, Texas & Pacific (T&P) Railway Company Surveys. Transactions prior to 1931 were not located by the County Clerk's Office or online. Historic maps and aerials were reviewed for additional information. A 1934 atlas of Taylor County identifies Section 6 of

Block 18 of the T&P RR lands as assigned to Theodore Heyck. According to the General Land Office (GLO) records, Heyck purchased 640 acres on April 7, 1893 (GLO 2019). The 1900 census records have Theodore Heyck in Abilene Ward 3, who was born in Jun 1825 in Germany (Ancestry 2019a). He immigrated to the US in 1852 and was not naturalized. His wife, Sophie, is recorded to have been born at sea in 1843 to German parents. His daughter, Annie, was born in 1876 in Texas. An earlier 1870 census shows that Heyck lived in Lavaca, Calhoun County with his wife, Sophie, son Adolph (3), and son, Theodore (1) (Ancestry 2019b). He was listed as a commission broker. His son, Theodore Jr., stayed in the area and married Francis Giraud Heyck in Harris County, Texas, where he died and was buried in 1925 (Find-a-Grave 2019a).

A 1940 map identifies the northwest quarter of Section 6, Block 18 as owned by G.R. Holloway and has a date of 5/7/31, which likely indicates that Holloway purchased the land in May of 1931 or was the listed owner of that property in May 1931. George R. Holloway was born in 1858 in Tennessee and died in 1933 in Merkel, Texas (Find-a-Grave 2019b). His wife, Virginia, was listed on the 1910 census as VT and born in Mississippi (Ancestry 2019c). They had six children ranging from 3 to 18 years old at home in 1910. Holloway was listed as a cattle and horse stockman and was self-employed in Merkel.

The exact transaction date and entity that Holloway purchased the approximately 160-acre property from is unknown at this time. A chain of ownership extending back to 1931 was provided by Lone Star NGL Pipeline LP for the property on which site 41TA397 is located (Appendix E).

Additional deeds were not found for this property during the search and a search of online records yielded the same result. Historic maps and aerials reveal that no houses or buildings were located within the boundaries of 41TA397 (Table 5-16). A topographic map dating to 1957 shows a structure located approximately 250 meters (820 feet) to the west, along CR 126 (NETR 2019). The structure is no longer present on maps dating after 1958 but two outbuildings are present until 1982. A search of the Handbook of Texas Online for the names of past landowners reveals that no persons of historical significance are associated with this site. Additionally, no historically significant events are known to have occurred at the location of site 41TA397 or in association with any persons listed on the chain of title.

Aerial Photo	1996	No buildings or structures; pond visible to the northeast of the site; surrounding land is visible as cultivated cropland with plow marks

Site Summary

The size of the scatter was not pursued beyond the limits of the APE. However, inspection of graded areas northwest of the site confirms no artifacts are located beyond the site limits within the APE. Within the APE, Resource 41TA397 is characterized by a sparsity of historic artifacts and truncated or deflated soils, which suggests the resource is not significant. Aside from one glass fragment located within 10 centimeters (4 inches) below surface within the plow zone, no other artifacts were obtained from shovel tests. In addition to being disturbed by plowing, the site is located near the road where material is often pushed and/or dropped as vehicles turn and is likely removed from its original location on the property. No further work is recommended for the location. The site portion located within the APE does not retain the potential to provide significant research value and is thus recommended not eligible for the National Register, under Evaluation Criterion D.

5.2.3.3 Resource 41TA398

Resource 41TA398 was identified by Horizon on April 11, 2019. The resource consists of a sparse surface scatter of lithic artifacts. The resource is located in Permit Area 12 on a relatively flat dissected upland approximately 100 meters (328 feet) south of CR 311 and 800 meters (0.5 miles) east of CR 1235, east of an ephemeral drainage and west of an unnamed tributary of Little Elm Creek (Figures 5-47 and 5-48). The APE at the location measures 40 meters (131 feet) wide, with approximately 30 meters (100 feet) of that amount within an existing pipeline corridor. The location at the time of survey consisted of a recently plowed field (Figure 5-34).

Figure 5-47. Location of Site 41TA398. View is to the east.

Surface materials observed by Horizon within the APE consisted 10+ flakes, four bifaces, one uniface, one utilized flake, and one scraper (Figures 5-49 and 5-50, Table 5-17). Flakes represented all stages, but most were primary or secondary and still displayed cortex. All materials were from created local chert (likely Edwards) and were gray to tan in color. Horizon noted that most of the materials were observed in the eastern half of the site. No diagnostic artifacts were identified. Horizon conducted 10 shovel tests within the scatter spaced roughly 30 meters (100 feet) apart, all of which were negative for buried cultural materials.

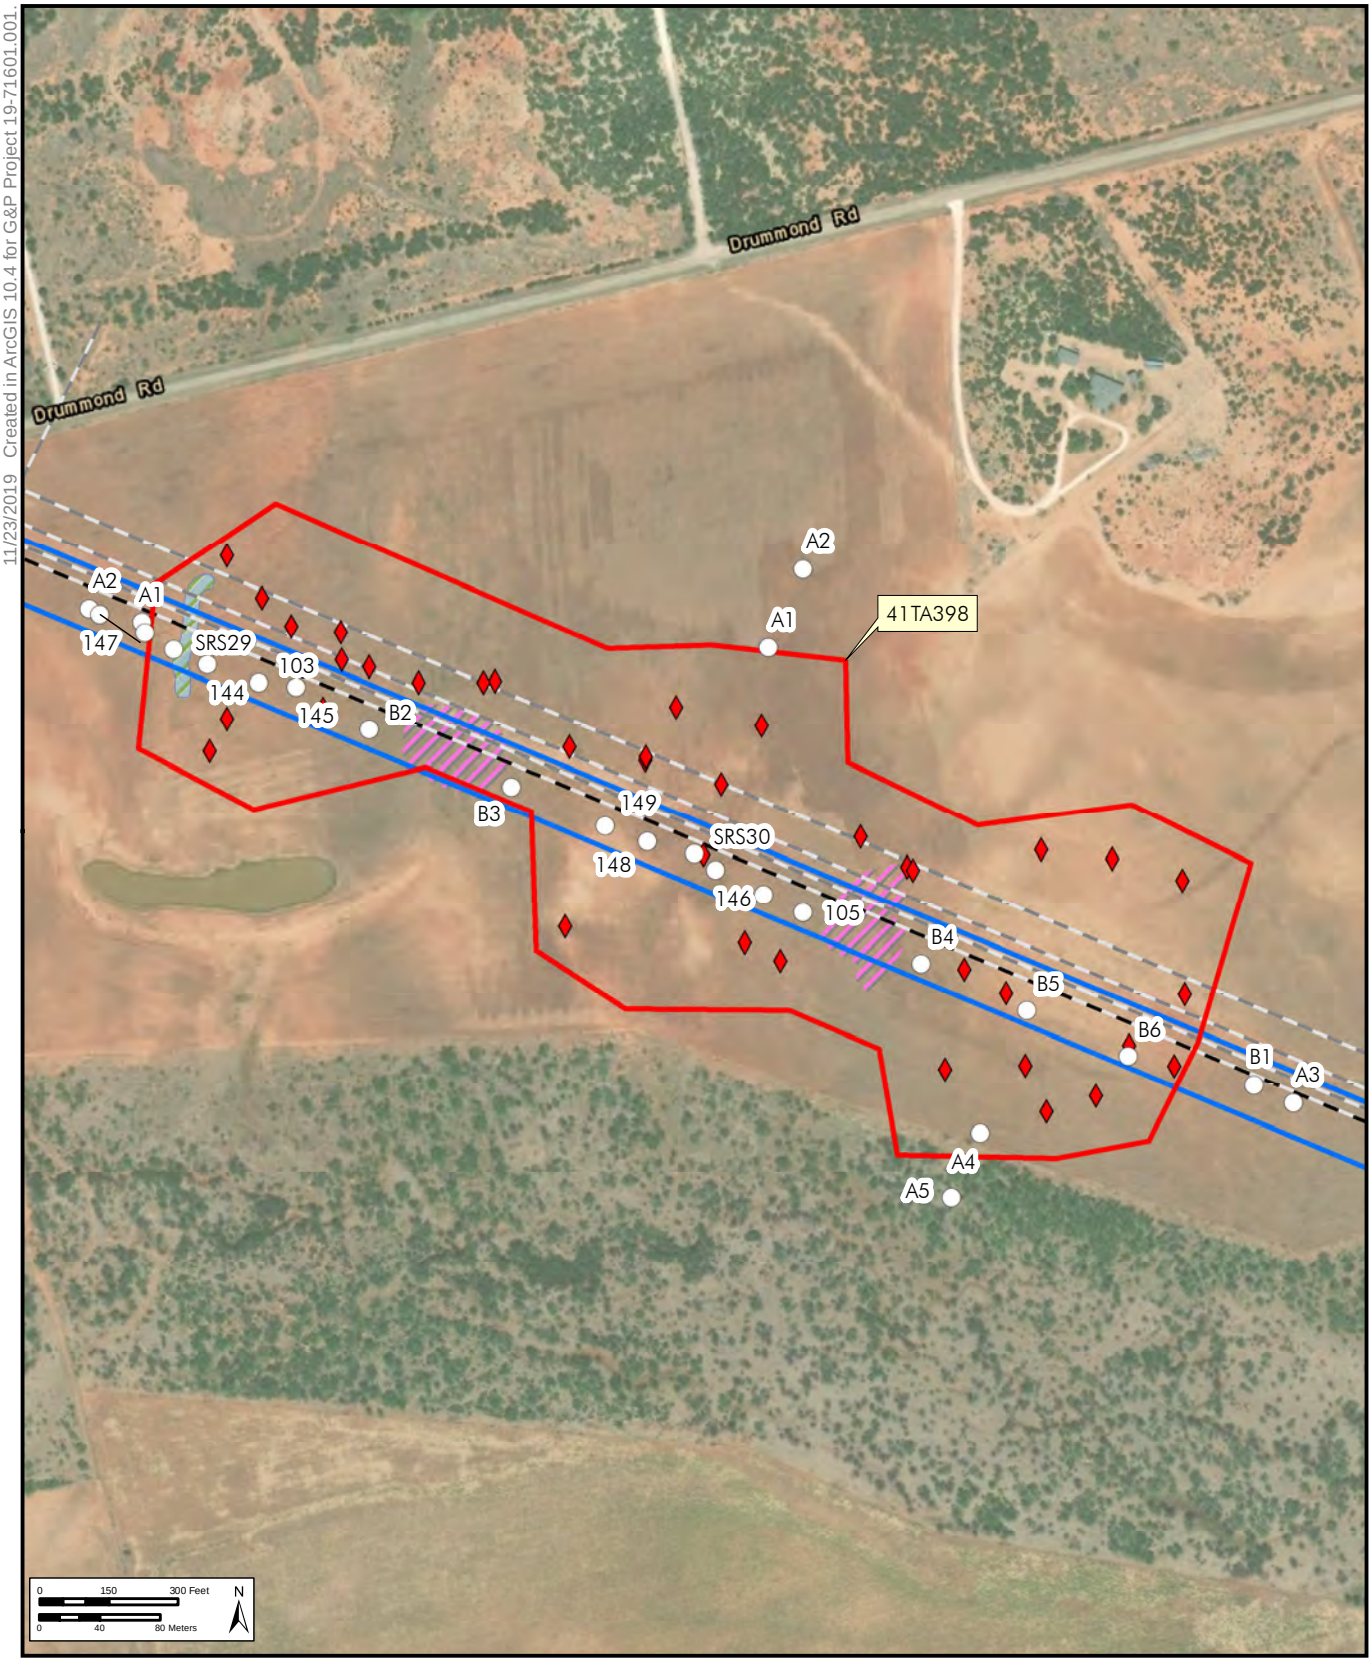

Figure 5-48

Figure 5-49. Representative flakes identified on the surface within Resource 41TA398.

Figure 5-50. Representative bifaces identified on the surface within Resource 41TA398.

On April 17, 2019, the site was revisited by Gray & Pape in an attempt to identify the site limits beyond the APE to the north and south. Investigation of the resource consisted primarily of pedestrian walkover and shovel tests on a judgmental basis outside the visual limits of the scatter. Gray & Pape observed an additional biface, six cores, and 24 flakes located outside of the APE to the north and south (Table 5-17). Gray & Pape conducted an additional six shovel tests within the site boundary/APE. All were negative for cultural materials. Gray & Pape also conducted four shovel tests to the north and south of the surface scatter outside of the APE. These were also negative for buried cultural materials. Of the 16 total shovel tests conducted within the limits of the scatter, none were positive for buried cultural materials.

The resultant boundary measures 752 meters (0.5 miles) northwest-southeast by 270 meters (886 feet) northeast-southwest with the extent of the resource extending a short distance beyond the ROW to the north and south. Soils mapped for the location consist of Tillman clay loam and Sagerton clay loam (NRCS 2019). These soils typically contain a shallow (18 centimeters [7 inches]) A horizon of brown (7.5YR 4/2, 4/3, 5/3 loam and clay loam. A typical shovel profile within the resource/APE consists of a surface layer of reddish brown (2.5YR 4/4) to yellowish red (5YR 4/6) silty clay loam to a depth of 10 to 30 centimeters (4 to 12 inches) followed by compact red (2.5YR 5/6) subsoil clay (Appendix C). This appears to represent the lower B or C horizon subsoils of the Sagerton or Tillman soils series. Some shovel tests contained bedrock underlying the clay at a depth of 30 centimeters (12 inches). This profile suggests the original surface of the location have been severely truncated.

Table 5-17. Artifact Assemblage Observed at 41TA398.

Depth	Flakes	Utilized flake	Bifaces	Unifaces	Cores	Scraper
Surface	34+	1	5	1	6	1
0-10	-	-	-	-	-	-

20-30	-	-	-	-	-	-
30-40	-	-	-	-	-	-
40-50	-	-	-	-	-	-

Site Summary

Resource 41TA398 is characterized by a number of surface artifacts that have likely been redeposited due to land modification and agriculture. No diagnostic materials were identified during survey. The soils at the location appear to be deflated/truncated due to agriculture and erosion. This combined with the lack of subsurface artifacts suggests the resource is not significant. No further work is recommended for the location. The site does not appear to retain the potential to provide significant research value and is thus recommended not eligible for the National Register, under Evaluation Criterion D.

5.2.3.4 Resource 41TA399

Resource 41TA399 was identified by Horizon on April 12, 2019. The resource consists of a surficial historic scatter and trash dump dating to the 1930s to 1950s. The resource is located in Permit Area 24 approximately 436 meters (0.3 miles) west of CR 106, on a very level ridgeline east of an intermittent drainage which flows into Cedar Creek (Figure 5-51). The APE at the location measures 55 meters (180 feet) wide. The location is sparsely wooded with several small push piles of brush and contains short grasses offering good surface visibility (Figure 5-51). The area appears to be used for cattle grazing as evidenced by many worn cattle paths through the location. The resource boundary measures approximately 120 meters (393.7 feet) east-west by 40 meters (131.23 feet) north-south.

Investigation of the resource consisted of pedestrian walkover and shovel tests excavated at between 10 and 30-meter (33 and 100-foot) intervals within the site (Figure 5-352). Observed materials include hundreds of fragments of glass, ceramics, metal, and other materials and a concentration of red brick (Table 5-18). These are discussed more below. Of the six shovel tests conducted within the resource/APE, none were positive for buried cultural materials.

Figure 5-51. Location of Site 41TA399. View is to the north.

Supplemental Investigation

Gray & Pape revisited the site on November 5, 2019 to perform additional delineation, map artifact concentrations, and collect additional information on diagnostic artifacts. Gray & Pape observed that the eastern portion of the site to the east contains a few metal items associated with cattle such as a feed trough, and associated farm implementation and downed barbed wire fencing. Many of the site's artifacts are located in the western edge and specifically contained within two concentrations (Figure 5-52). A total of nine supplemental shovel tests were conducted within the site boundary/APE to complete delineation. Five of those tests were conducted as part of investigation of two concentrations of artifacts. These are described in more detail below. In addition to the supplemental shovel tests, a cut bank along the waterway to the west was inspected for deeper materials or features.

The first concentration observed is a scatter of pressed bricks, stamped "ABILENE" (Figures 5-53 and 5-54). The concentration measures approximately 6 meters (20 feet) long by roughly 6.5 meters (21 feet) wide or 38 square meters (409 square feet). The concentration is located at the edge of the upland, just before a drop to a lower terrace. The brick is primarily on the surface although some have sunk into the

ground slightly or have been trampled in by cattle. There are no other materials within the concentration that appear to be directly associated with the brick. Four shovel tests were placed in the area of the brick: one in the center (S1) and 3 around the perimeter (tests S2, S3, and 122). None were positive for additional materials below surface. Based on this, the brick does not appear to represent an in-situ feature.

Figure 5-53. Brick scatter within Resource 41TA399. View is to the north.

Figure 5-54. Red brick stamped "ABILENE."

The second concentration is composed of hundreds of glass, metal, and ceramic fragments spread over a narrow low terrace at the west edge of the site. The concentration measures approximately 25 meters (82 feet) long and 9 meters (29.5 feet) or approximately 217 square meters (259.5 square yards). The terrace is highly deflated with subsoil, gravels, and rock on the surface amidst the historic materials. A single shovel test was attempted within the scatter but was terminated after only 8 centimeters (3 inches) by the density and hardness of the soil. A total of 15 shovel tests were excavated as part of site delineation. None contained buried cultural materials. No testing was conducted outside of the site boundary to the east. This area is a sparsely vegetated fallow ag field which shows clear signs of subsoil at the surface. The centerline where it passes the site is partially overlapped by a rutted access road. The road ruts were inspected for materials and shovel tests were placed along the centerline where it passes the site, but this area was highly deflated and eroded. Tests immediately contacted compact subsoil.

Table 5-18. Artifact Assemblage Observed at 41TA399.

Depth	Glass	Historic Ceramics	Brick	Metal
Surface	400+	100+	30	25
0-10	-	-	-	-
10-20	-	-	-	-
20-30	-	-	-	-
30-40	-	-	-	-
40-50	-	-	-	-

Soils mapped for the location consist of Colorado soils and Sagerton clay loam which generally have a surface layer of brown (7.5YR 4/2) clay loam or light reddish brown (5YR 6/3) loam (NRCS 2019). A typical shovel profile within the resource/APE consists of heavily compacted red to strong brown (2.5YR 4/6 to 7.5YR 5/6) clay to a maximum depth of 30 centimeters (12 inches) followed by bedrock (Appendix C). This soil profile was verified in the cut bank west of the site, which contained a uniform 7.5YR 5/6 clay to a depth of 1 meter (39 inches). This profile suggests a B horizon of the Sagerton soil series.

Diagnostic Artifact Analysis

Historic artifacts observed at Site 41TA399 date to the mid to late 20th century as evidenced by color, seams, finish, and makers marks. Among

the assemblage are artifacts that include clear, brown, green, blue, and purple bottle glass, soda bottle base and neck fragments, milk glass jars, whiteware and other ceramics, vulcanized rubber fragments, an embossed white metal plate, a notched aluminum strip, metal can fragments, a drawer pull, a carbon rod from a battery, galvanized metal and aluminum fragments, and a concentration of red brick.

While there were many styles of brick made by the Abilene Pressed Company (renamed Abilene Brick Company in 1936) the style of Abilene brick observed at the site is modern and likely dates post WWII. The plant was in business until 1980 (Arrick/Orrick Genealogy 2019; Newspapers.com 2019). Other diagnostic artifacts are detailed in Table 5-19 and Figures F-55 to 5-62 below.

Table 5-19. Diagnostic historic artifacts observed at Site 41TA399.

Figure	Artifact	Comments
5-55	Clear bottle with the Owens-Illinois Glass base maker's mark	Maker's mark dates between 1929 -1954 (Toulouse, Julian Harrison; 1971 p403). Applied label dates to post-1935 (Deiss 1981:95).
5-56	Glass cosmetic jar, press molded, opaque white with continuous threaded finish, external	Continuous thread date to post 1919 (Deiss 1981:95; Leif 1965:29). Likely 1950s (Lindsey 2019).
5-57	Glass bottle, amber with embossed lettering and continuous thread finish	Listerine was prescription only until 1914. This bottle post-dates 1914 (Lindsey 2019).
5-58	Earthenware, Fiestaware, yellow	First manufactured by The Homer Laughlin China Company in 1936. (Huxford and Huxford 1984) (https://fiestafactorydirect.com/pages/our-history 2019).
5-59	Glass bottle, amber with maker's mark	Maker's mark D9 68 50 DES PAT. 128624. Patent filed by E. L. Du Pree of Chappaqua, NY on May 14, 1941. Patented Aug 5, 1941.
5-60	Glass cosmetic jar, press molded, opaque white with maker's mark	Maker's mark: MENTHOLATED 12 REG TRADE MARK. Yucca Company founded in 1889, Mentholated first produced in December 1894. Jar likely dates to the 20th century.
5-61	Furniture knob; pressed glass	19th to 20th century manufacture.
5-62	Earthenware vessel, whiteware with blue annular banding	Two blue painted annular bands. Likely 19th century.

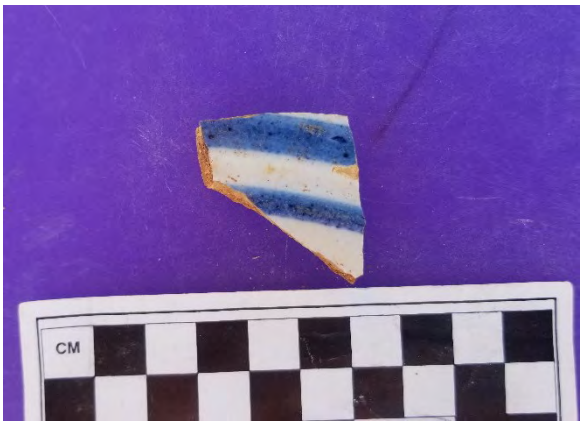

Figure 5-62. Blue annular banding on whiteware vessel.

Other artifacts that were not necessarily diagnostic but are important to note are a metal spoon and knife (Figure 5-63 and 5-64), and a thin metal band with rounded edges, that bore a decorative stamp for the Texas Centennial flanked by the dates 1836-1936. Much of the identified materials have an estimated date range from the 1910s-1950s with a few older pieces.

Figure 5-63. Metal spoon.

Figure 5-64. Metal tableware knife.

Archival Research

Archival research of the property was undertaken. A limited title search was conducted by Lone Star NGL Pipeline LP by the Taylor County Clerk's Office. The property is located on Highway 204 in Taylor County and was originally part of the Lunatic Asylum Lands. The current parcel (Property ID 109134) is part of Abstract 1258 and contains 48.283 acres in SE quarter of Section 26 of the Lunatic Asylum Lands. These lands were assigned by the Legislature on August 30, 1856 as part of an act which set apart and appropriated land for multiple Asylums and allocated 100, 000 acres of land to each institution. These lands were surveyed in Callahan, Comanche, Eastland, Jones, Shackelford, Stephens, Taylor, and Tom Green counties (Gammel 1898). Transactions prior to 1945 were not located by the County Clerk's Office or online (Table 5-20). Historic maps and aerials were reviewed for additional information (Table 5-21). A 1934 atlas of Taylor County identifies the southeast quarter of Section 26 of the Lunatic Asylum Lands as assigned to L.J. Gould. According to the General Land Office (GLO) records, Gould purchased 160 acres in the southeast quarter of Section 26 on March 15, 1884 (GLO 2019). A 1940 map identifies the southeast quarter of Section 26 of the Lunatic Asylum Lands as owned by G.A. Chrone. No information regarding either L.J. Gould or G.A. Chrone could be located in a genealogical records search.

Table 5-20. Deed Research Results for 41TA399.

Grantee	Grantor	Grantor Sell Date	Description Type; Deed Volume/Page	Additional Information
Lone Star NGL Pipeline LP	Anton and Kim Melnyk	5/9/2006	Permanent Easement Agreement; 3226/662	
Anton and Kim Melnyk	Tommie and Cecil Allen	5/8/2006	Warranty Deed; 3226/662

Tommie Allen and Donald R. Grubbs	Estate of Lucille A. Grubbs, deceased	1/27/1992	Probate – Application for Probate of Will as Muniment of Title; 295/684	Tommie and Donald are siblings – children of Lucille A. Grubbs; each received 50% interest – power of attorney granted on March 6, 1991
	Cecil and Tommie V. Allen	4/20/1976	Affidavit; 1027/949	States that the 2 acres, out of 52-acre tract, SE corner, Sec. 26, Lunatic Asylum Lands, is their homestead
Cecil and Tommie V. Allen	Troy Tony and Lucille Grubbs	6/24/1964	OUTSALE: Warranty Deed; 746/27	Conveys 2 acres out of 52-acre tract out of 120 acres out of SE corner of Sec. 26, Lunatic Asylum Lands
Troy Tony and Lucille Grubbs	Novel and Vida M. Baize	12/12/1962	Warranty Deed with Vendor's Lien; 697/411	Earlier deed is almost identical dated 4/24/1962 (677/223)
State Highway Commission	George D. and Alesa Kiker	5/25/1954	Deed; 485/524	Parcel B: 1.84 acres of which 1.011 acres are present in county road
George D. and Alesa Kiker	C.A. McGaughey et aux	10/15/1945	Deed; 339/289	

A chain of ownership extending back to 1945 was provided by Lone Star NGL Pipeline LP for the property on which site 41TA399 is located (Appendix F). Additional deeds were not found for this property during the search and a search of online records yielded the same result. Historic maps and aerials reveal that no houses or buildings were located within the boundaries of 41TA399. A search of the Handbook of Texas Online for the names of past landowners reveals that no persons of historical significance are associated with this site. Additionally, no historically significant events are known to have occurred at the location of site 41TA399 or in association with any persons listed on the chain of title.

Table 5-21. Historical maps and aerials for 41TA399.

Type	Date	Notes
GLO Map	1859	Land assigned as Sec 26 of Lunatic Asylum Lands – no individual owner; East Fork of Red Creek runs north-south through western half of section
GLO Map	1879	Sec 26 of Lunatic Asylum Lands, unassigned to an individual but shown on map with four quarter file numbers labeled as 2213 (in NW), 2385 (in NE), 2340 (in SE), and 2212 (in SW)
GLO Map	1883	Sec 26 of Lunatic Asylum Lands, unassigned to an individual but shown on map with four quarter file numbers labeled as 2213 (in NW), 2385 (in NE), 2340 (in SE), and 2212 (in SW)
Abilene Quad Topo Map	1890	Cedar Creek to the west and a drainage to the east; no buildings or activities within site
Soil Survey Map	1922	Abilene & Southern Railroad, Cedar Creek, and road in general vicinity of modern FM 126 to the west of site, road in general vicinity of modern FM 1750 to south; no buildings or activities within site
Atlas Map	1934	Section 26 of the Lunatic Asylum Lands assigned to L.J. Gould
Atlas Map	1940	Section 26 of the Lunatic Asylum Lands assigned by G.A. Chrone
Kirby Lake Quad Topo Map	1957	Drainage shown to the west and ponds to the north and south; site appears on edge of drainage field/wetland; current configuration of roads visible, building to southeast of site on the west side of Key Lane; no buildings or activities within site boundaries
Aerial Photo	1967	No buildings or structures; pond visible to the south of the site; surrounding land is visible as undeveloped land with vegetation; land to east is cultivated farmland with dirt roads and plow marks
Atlas Map	1972	No buildings or structures within site; buildings along FM 602 to north, two buildings along west side of FM 106, and two on the south side of Clark Road
Atlas Map	1982	No buildings or structures within site; multiple buildings along FM 602 to north, to east along FM 106, south along Clark Rd, and west along FM 126 and in the El Dorado Addition
Aerial Photo	1994	No buildings or structures; pond visible to the north of the site; surrounding land is visible as undeveloped land with dense vegetation; land to east is cultivated farmland with dirt roads and plow marks
Aerial Photo	2002	No buildings or structures; surrounding land is visible as undeveloped land with dense vegetation; land to east is cultivated farmland with plow marks

The 1967 aerial and 1958 topographic map show a structure located alongside CR 106. That structure appears to have been replaced with a modern structure that occupies the location. It's possible these materials date to the time of the earlier structure but it is impossible to say with certainty.

Site Summary

The resource may extend north of the corridor, but this area was not investigated. However, within the corridor, the resource is characterized by surface artifacts that are certainly displaced and lack of subsurface deposition. The location is severely deflated, and subsoil and numerous gravels and rock is encountered immediately. While producing several artifacts, the resource is not likely to add any additional information to the knowledge of historic occupation of the area beyond what has been recorded and is not recommended for further work. The site does not appear to retain the potential to provide significant research value and is thus recommended not eligible for the National Register, under Evaluation Criterion D.

5.2.3.5 Resource 41CA42

Resource 41CA42 was identified by Gray & Pape on April 4, 2019. The resource consists of a low-density surficial lithic scatter. The resource is located in Permit Area 39 approximately 0.88 kilometers (0.55 miles) west of CR 309, approximately 26 meters (85 feet) west of a wetland associated with Club Hollow Creek, and less than 5 meters (16.4 feet) east of a two-track road (Figure 5-65). The location is on gently sloping terrace that is currently scrub brush pasture and is sparsely covered by grasses and a great deal of rock at the surface, offering good surface visibility (Figure 5-66). The APE at the location measures 40 meters (131 feet) wide, with approximately 30 meters (100 feet) of that width located within an existing pipeline ROW. The resource boundary within the corridor measures 80 meters (262.47 feet) east-west by 30 meters (98.43 feet) north-south. A clear line of redeposited larger rocks was observed at the edge of the ROW within the APE. These consist of the results of back dirt sifting prior to backfilling the previous pipeline trench. The larger rocks are removed during the process, so they don't damage the pipe when the soil is backfilled on top of the pipe. Observed surface artifacts were comprised of approximately ten flakes, three chert cores, and one worked flake (Figure 5-67, Table 5-22). All the material was of local chert (Edwards) of gray to tan color. Flakes were largely of early stage as evidenced by cortex.

Table 5-22. Artifact Assemblage Observed at 41CA42.

Depth	Flakes	Cores	Work Flake
Surface	13	3	1
0-10	-	-	-
10-20	-	-	-
20-30	-	-	-
30-40	-	-	-
40-50	-	-	-

Supplemental Investigation

The site was initially only investigated by surface inspection as no shovel tests were allowed on the property per the landowner's request. Gray & Pape revisited the location on October 3, 2019 after the easement had been purchased for the project. A total of nine supplemental shovel tests were excavated in the location: four within the site and five surrounding. None of the shovel tests contained buried cultural materials.

Soils mapped for the area consist of Lueders-Speck association which consists of a shallow gravelly clay loam derived from residuum from indurated limestone (NRCS 2019). The typical soils profile of the association consists of A and B horizons of gravelly and cobbly clay to a depth of 33 centimeters (13 inches) before encountering fractured layered limestone.

- Negative Shovel Test

Figure 5-66. Location of Site 41CA42. View is to the northwest.

Figure 5-67. Representative materials identified on the surface within Resource 41CA42.

Shovel tests conducted at the site exhibited shallow surface layers of reddish brown (5YR 4/3) silt loam to an average depth of 10 centimeters (4 inches) followed by a layer of bedrock. A few tests exhibited a second stratum consisting of dark reddish brown (5YR 3/2 to 3/3) silty clay to a maximum depth of 28 centimeters (11 inches) followed by bedrock.

Agency Revisit

The site was revisited by Gray & Pape and representatives of the USACE on October 29, 2019. During a walk over USACE observed three chert flakes, high surface visibility, and frequent rock exposure at this site. One flake observed during the visit appeared to be a blade, located outside of the site boundary to the east.

Site Summary

A nearby Isolate Find, CA-39-ISO-02, is likely associated with the site (discussed below). This find consists of a biface identified on the surface and is discussed later in the report. A small number of other artifacts were also observed east of the site during the agency visit in late October. However, the majority of the observed materials, although sparse, were identified west of the waterway within the site boundary as currently mapped (Figure 5-65). All of the artifacts are out of context. Of four shovel tests conducted within the site boundary, none were positive for cultural materials. The resource appears to have experienced moderate impacts from the previous pipeline installation. A great deal of bedrock is exposed on the surface and soils are quite shallow. This combined with the lack of subsurface artifacts suggests the resource is not significant. No further work is recommended for the location. The site does not appear to retain the potential to provide significant research value and is thus recommended not eligible for the National Register, under Evaluation Criterion D.

5.2.3.6 Isolate CA-39-ISO-02

Isolated Find CA-39-ISO-02 was identified by Gray & Pape on April 4, 2019. The find consists of a single chert biface of local material (likely Edwards) (Figure 5-68) that was discovered on the ground surface during pedestrian walkover. The find is located approximately 110 meters (361 feet) east-southeast of resource 41CA42, within a low grassy wetland associated with Club Hollow Creek (Figure 5-65). Initially, the location was only subjected pedestrian walkover.

Supplemental Investigation

Supplemental investigation was conducted on October 3, 2019 after the easement had been purchased for the project. This resulted in the excavation of six shovel tests: one at the find and five surrounding the location. Soils mapped for the area consist of Lueders-Speck association which consists of a shallow gravelly

clay loam derived from residuum from indurated limestone (NRCS 2019). The typical soils profile of the association consists of A and B horizons of gravelly and cobbly clay to a depth of 33 centimeters (13 inches) before encountering fractured layered limestone. Shovel tests resulted in a soil profile of an extremely shallow (5 centimeters [1 inch]) layer of reddish brown (5YR 4/3) silty loam followed by bedrock (Appendix C). This appears to verify the lack of soil deposition at the site.

Figure 5-68. Biface identified on the surface representing Isolate CA-39-ISO-02.

Shovel test delineation of the find did not identify cultural material exist at the location. The naturally occurring shallow soils at the location have been eroded further by previous pipeline impacts. The find is not likely to add to the knowledge of prehistoric occupation of the area and is not recommended for further work. The isolate does not retain the potential to provide significant research value and is thus recommended not eligible for the National Register, under Evaluation Criterion D.

5.2.3.7 Resource 41CA43

Resource 41CA43 was identified by Gray & Pape on April 12, 2019. The resource consists of a low-density lithic scatter of unknown prehistoric affiliation. The resource is located in Permit Area 58 approximately 1.24 kilometers (0.77 miles) east-southeast of CR 880, within the existing pipeline corridor on a dissected upland with a gentle slope to the north side of a small intermittent drainage extending from Battle Creek (Figure 5-69). The APE at the location measures 40 meters (131 feet) wide, with approximately 30 meters (100 feet) of that width located within an existing pipeline ROW. The resource boundary within the APE measures approximately 40 meters (131.23 feet) northwest-southeast by 10 meters (32.8 feet) northeast-southwest and occupies a small raised landform and adjacent slope.

Beyond the site boundary, the ground slopes down to the north, south, and west. The west edge of the APE drops off into a wooded area where some cuts caused by erosion have exposed the soil horizons along the edge of the APE. The southern portion of the site has a high degree of slope down to the waterway which has allowed a great deal of limestone to be exposed. The area is covered by short grass, scrub brush, and exposed limestone bedrock which allowed excellent surface visibility (Figure 5-70).

Investigation of the resource consisted of pedestrian walkover and shovel testing. Observed surface artifacts consist of 10 fine-grained chert flakes of local (likely Edwards) material of gray/white color (Figure 5-71, Table 5-23). Most were composed of early stage manufacture as evidenced by cortex. These were found within the existing pipeline ROW. No diagnostic artifacts or more developed tools were identified. A large cobble of what appeared to be quartz was located on the site but was not worked. Attempts at shovel testing the location were hindered by the preponderance of limestone bedrock on the surface. Further, the site scatter is entirely located within the existing pipeline ROW adjacent to previously installed pipelines. However, five shovel tests were excavated surrounding the site: four west of the site boundary along the APE at 30-meter (100-foot) intervals within the APE, and one east of the site at the edge of the APE (Figure 25). None of the tests were positive for cultural materials.

Agency Revisit

The site was revisited by Gray & Pape and representatives of the USACE on October 29, 2019. During a walk over USACE observed approximately 12 flakes, all similar white chert, across the surface of 41CA43. Eight flakes of the same raw material were in a very small (less than 25-centimeter [10-inch]) concentration within the known boundary of 41CA43, and inside the maintained ROW of an existing pipeline. While this at first appeared to be a discreet lithic reduction feature, it was later determined to be the location where artifacts from the previous investigation in April 2019 had been gathered for photographs and discarded. This was confirmed through a comparison with the artifact photos (Figure 5-71) and discussion with crew personnel of the previous investigation. However, due to the limited size of the landform the artifacts were originally found close-by in the general vicinity, thus the location was shovel tested during supplemental investigation of the site as discussed further below.

USACE observed a sandy matrix across the entire surface of 41CA43 with no bedrock exposure accept inside small erosional/stream features where the stream bed contained sandstone bedrock (these features appear outside the 41CA43 boundary). It was the opinion of the USACE representative that inside the 41CA43 boundary the sandy matrix is supported to have a depth of at least 25 to 50 centimeters (10 to 20 inches) based on soil profiles USACE observed along the edge of the maintained pipeline ROW. A classic sandy matrix with soil horizons A-E-Bt in the soil profile was visible at various profile exposures just outside of the 41CA43 site boundary.

Supplemental Survey

Gray & Pape revisited the site location on November 5, 2019 to perform additional delineation of Site 41CA43. An additional 11 shovel tests were excavated across the location: five within the site boundary and six surrounding it. One shovel test (S1) was placed at the location of what appeared to be a small lithic reduction workspace as identified during the agency revisit in October.

Soils mapped for the location consist of Cisco-Hext-Pedernales association which typically contain a shallow (10-centimeter [4-inch]) surface layer of brown (7.5YR 5/4) loamy fine sand before successive layers of yellowish red (5YR 4/6) sandy clay loam subsoil (NRCS 2019). Overall, tests located within the site boundary and along the centerline typically contained a very shallow (10 to 15-centimeter [4 to 6-inch]) layer of pink (7.5YR 7/4) compact sandy loam before encountering multicolored compact clay subsoil / consolidated sandstone. This likely represents the BCk - Cr horizons of the Hext soil series, which is mapped for the location. This result and the presence of limestone at the surface suggests the location has been highly eroded. Pipeline personnel who accompanied the agency and supplemental site visit stated that the location had been previously graded and truncated, resulting in an artificially leveled landform (Patrick Hill personal communication October 29, 2019).

As observed by the USACE representative, shovel tests placed along the western edge of the APE above the drop-off into the wooded area contained a slightly thicker (25 centimeters [10 inches]), or more natural sandy upper stratum (Appendix C). This is likely the closest the location comes to what used to be the natural soil profile. However, shovel tests all along the western edge of the APE produced no cultural materials.

Site Summary

The resource is characterized by a sparsity of surface artifacts and lack of diagnostic artifacts. Shovel testing within the site boundary and along the centerline of the location produced a lack of soil deposition. This seems to confirm the statement made by pipeline personnel that the area had been truncated. Of a total of five shovel tests conducted within the site boundary, none were positive for cultural materials. This suggests that the resource within the ROW is not significant. No further work is recommended for the location. The site portion located within the APE does not retain the potential to provide significant research value and is thus recommended not eligible for the National Register, under Evaluation Criterion D.

5.2.4 Newly Identified Isolates within Jurisdictional Areas

5.2.4.1 Two new isolates were identified as a result of survey within jurisdictional permit areas in Loop 2. One isolate, CA-039-ISO-02 was discussed above (pg. 69) along with Resource 41CA42. The other is Isolate TA-50-ISO-01.

5.2.4.2 Isolate TA-50-ISO-01

Resource TA-50-ISO-01 was identified by Horizon on April 11, 2019. The resource consists of two flakes (one utilized) identified at the surface and within a shovel test at a depth between 0 and 10 centimeters (0 and 4 inches) (Figure 5-72). The resource is located 500 meters (0.31 miles) southeast of Resource 41TA398 within an area of mesquite brush that lines a small meander surrounded by agricultural fields. The APE at the location measures between 40 and 55 meters (131 and 180 feet) wide. Approximately 30 meters (100 feet) of that width is within an existing pipeline corridor (Figure 5-43). Investigation of the resource consisted of pedestrian walkover and three delineation shovel tests placed around the lone positive test at between 10 and 20-meter (33 and 66-foot) intervals within the APE (Figure 5-73).

Positive Shovel Test
Negative Shovel Test

GRAY & PAPE
HERITAGE MANAGEMENT

Soils mapped for the location consist of the Colorado series which typically contain an A horizon of light reddish brown (5YR 6/3) silt loam (NRCS 2019). The shovel test profile of the lone positive test consists of a surface layer of dark reddish brown (5YR 3/2) clay loam followed by yellowish red (5YR 4/6) silty clay loam subsoil with stream gravel inclusions. This suggests the soils at the surface are composed of the C horizon of the Colorado series. None of the excavated tests were positive for cultural materials. No additional cultural materials were identified on the surface near the find.

The shallow depth of the find is likely the result of previous pipeline or agricultural impacts or natural taphonomic processes such as cattle trampling. The isolate is not recommended for further work. The isolate does not retain the potential to provide significant research value and is thus recommended not eligible for the National Register, under Evaluation Criterion D.

5.2.5 Revisit Results of Identified Previously Recorded Non-Jurisdictional Resources

In addition to revisits of previously recorded resources located in permit areas, one previously recorded resource, Site 41TA371, is located within 91 meters (300 feet) of the APE along non-jurisdictional uplands.

5.2.5.1 Resource 41TA371

Resource 41TA371 was originally recorded by Burns and McDonnell Engineering in 2018. The resource was described as an 80- by 50-meter (262- by 164-foot) historic scatter located in a plowed agricultural field. Material noted at the time included brick, glass, miscellaneous metal, and a spark plug. Material was limited to the ground surface and no diagnostic material or cultural features were identified. The site was recommended as not eligible for listing on the NRHP (Darnell et al. 2018).

Resource 41TA371 was revisited by Horizon on April 12, 2019. The location is in a level agricultural field (Figure 5-74) approximately 20 meters (787 feet) west of Permit Area 18. The APE at the location measures 40 meters (131 feet) wide, of which nearly all is within the existing pipeline ROW (Figure 5-75). The area has been impacted by plowing and existing pipelines. Investigation of the resource consisted of pedestrian walkover and the excavation of three shovel tests within the APE south of the previously recorded site boundary. One piece of glass and one chert scraper were observed on the ground surface within the APE. All shovel tests were negative for cultural resources.

Figure 5-74. Overview of 41TA371. View is to the east.

Soils mapped for the location consist of Clairemont silty clay loam which generally contain a surface layer of reddish brown (5YR 5/4) silt loam (NRCS 2019). A typical shovel profile within the resource/APE consisted of a surface layer of yellowish red (5YR 5/8) silty sand to a depth of 10 centimeters (4 inches). This was underlain by yellowish red (5YR 4/6) dense sandy clay to 25 centimeters (10 inches), followed by a loose yellowish red (5YR 4/6) sandy clay to a depth of 70 centimeters (27 inches) below the surface. This soil profile suggests the soils at the location have been displaced or truncated.

As a result of the two surface finds, the boundaries of site 41TA371 were initially expanded extended south to include an area of 90 by 50 meters (295 by 164 feet) within the

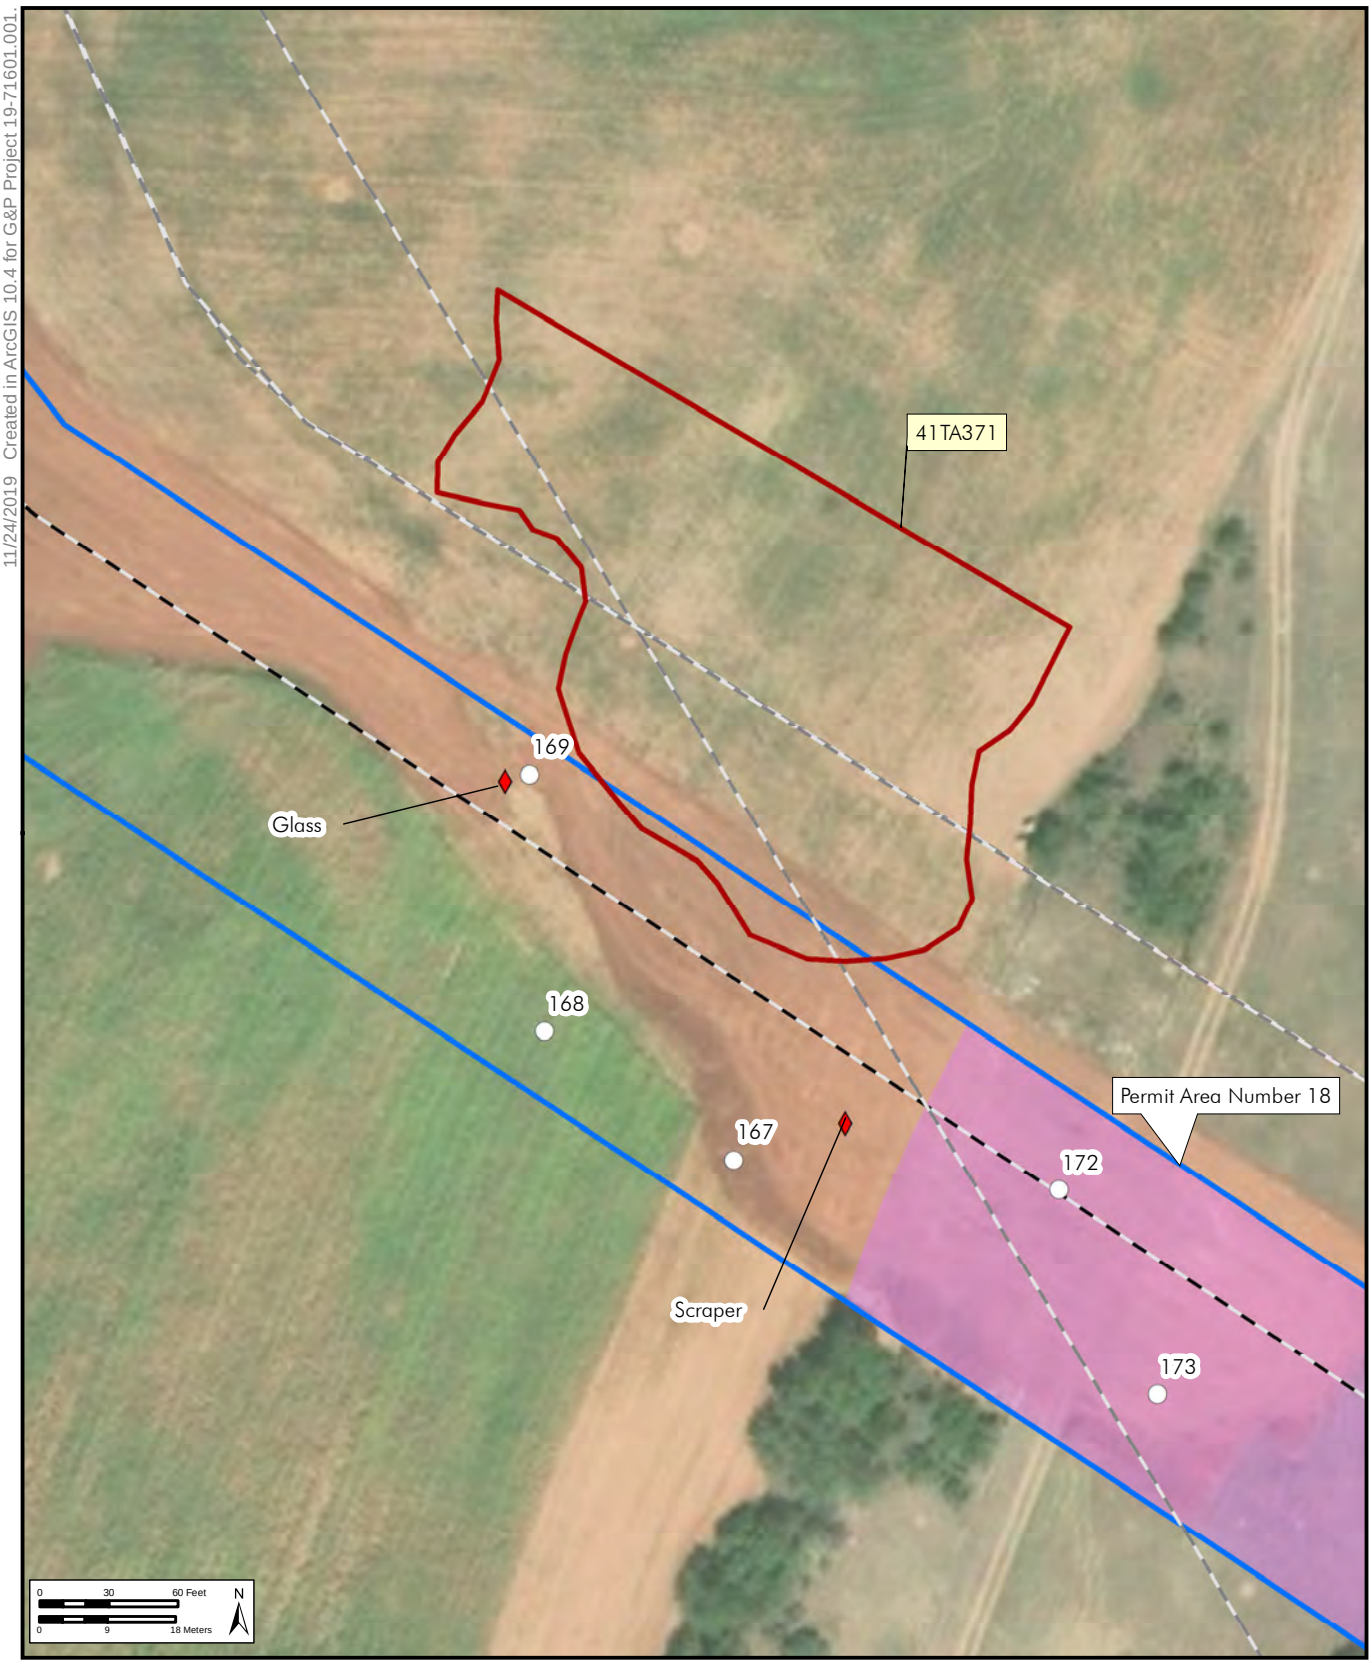

Figure 5-75

current ROW. However, upon review of the data provided by Horizon, sparsity of material identified, and the redeposited context of the artifacts, Gray & Pape does not recommend the site boundary be expanded to include these artifacts. The lack of additional materials and the deflated/truncated soils of the location suggest the find is not significant. No further work is recommended for the location.

5.2.6 Deep Test Results

Fieldwork at Mulberry Creek was conducted on August 6, 2019. The permit area (Number 6) at Mulberry Creek is located approximately 4.27 kilometers (2.65 miles) south-southeast of Merkel, Texas, and subsumes approximately 18.47 acres (7.47 hectares) (Figure 5-50). Soils mapped in this area consist of Gageby clay loam (Ga), Colorado soils (Cr), Knoco-Badland complex (ObE), and Tillman clay loam (TmB) (NRCS 2019).

Gageby soils are very deep, well drained, moderately permeable mollisols that formed in calcareous, loamy alluvium. A typical soil profile consists of five strata (Ap-A-Bwl-Bw2-BCk) that extend to 203 centimeters (80 inches) below the surface. The profile includes a surface layer (A horizon) of brown (7.5YR 4/2) clay loam to a depth of 18 centimeters (7 inches). That is followed by a subsurface (A2 horizon) of brown (7.5YR 4/2) sandy clay loam to a depth of 61 centimeters (24 inches). Below that is successive B horizons of yellowish red (5YR 5/6) sandy clay loam to a depth of 203 centimeters (80 inches) (NRCS 2019).

The Colorado series is comprised of very deep, well drained, moderately permeable entisols that formed in calcareous loamy alluvium. These nearly level soils can be found on flood plains. A typical soil profile consists of three strata (A-C1-C2) to a depth of 152 centimeters (60 inches). A typical profile includes a surface layer (A horizon) of light reddish brown (5YR 6/3) silt loam to a depth of 13 centimeters (5 inches). That is followed by successive C horizon layers of light reddish brown (5YR 6/3) loam to a depth of 152 centimeters (60 inches) (NRCS 2019).

The Knoco series consists of very shallow to shallow, well drained, very slowly permeable entisols that formed in residuum weathered from claystone over Permian-aged noncemented claystone bedrock. These soils are located on interfluves, side slopes and erosional footslopes on dissected plains. A typical soil profile consists of five strata (A1-A2-C-Cd1-Cd2) to a depth of 152 centimeters (60 inches). The profile includes a surface layer (A horizon) of red (2.5YR 4/6) clay to a depth of 13 centimeters (5 inches). That is followed by a subsurface (A2 horizon) layer of reddish brown (2.5YR 5/4) clay to a depth of 23 centimeters (9 inches). Below that is successive subsoil (C horizon) layers of reddish brown (2.5YR 4/4 to 5/4) of dense clay and noncemented claystone to a depth of 152 centimeters (60 inches) (NRCS 2019).

The Tillman series consists of very deep, well drained, slowly permeable mollisols. These soils formed in loamy and clayey alluvium derived from redbed clays and claystone sediments of Permian age. Tillman soils can be found on nearly level to gently sloping alluvial plains and alluvial plain remnants of the Central Rolling Red Plains and Rolling Limestone Prairie. A typical soil profile consists of nine strata (A1-A2-Bt1-Bt2-Btk1-Btk2-Btk3-2BCk-2Cr) to a depth of 216 centimeters (85 inches). The profile includes a surface (A horizon) layer of brown (7.5YR 5/3) loam to a depth of 8 centimeters (3 inches). That is followed by a subsurface (A2 horizon) layer of brown (7.5YR 4/3) clay loam to a depth of 18 centimeters (7 inches). Below that are successive subsoil (B horizon) layers of reddish brown (5YR 4/3 to 4/4) clay to a depth of 203 centimeters (80 inches). The following layer consists of red (2.5YR 4/8) clay loam to a depth of 216 centimeters (85 inches) (NRCS 2019).

GRAY & PAPE
HERITAGE MANAGEMENT

At least three shovel tests at the location (B1, B3, and B4) contained soils that continued beyond the depth of the shovel tests (1 meter [39 inches]) and could represent A horizon material (Appendix C). The location was thus recommended for deep testing by the Field Archaeologist. This recommendation in tandem with the geomorphological data mapped for the location resulted in the area being deep tested. Field investigations consisted of deep testing by means of mechanical augur attached to a Bobcat (Figure 5-76). Each test measured 38.1 centimeters (15 inches) in diameter. A total of 15 auger tests were attempted (Figure 5-77). Two tests were not able to be conducted for reasons described below.

The proposed location of Deep Test (DT) 5 could not be entered due to the thickness of the mesquite. A shovel test was conducted at the location instead. The proposed location of DT7 was not able to be excavated due to the location being essentially cut off from the rest of the ROW by the winding of Mulberry Creek. There was no means to access the location without traveling outside of the APE, which was not permitted by the landowner.

Figure 5-77. Deep testing in progress within the Permit Area 6 at Mulberry Creek. View is to the northwest.

Although tests differed slightly while moving across the permit area, a typical deep test profile (Table 5-25) within the permit area consists of a surface layer of yellowish red (5YR 4/6 or 5/6) silty clay loam to an average depth of 50 centimeters (19.7 inches) followed by yellowish red (5YR 5/6) silty clay or silty clay loam extending to an average depth of 135 centimeters (53 inches) (Figure 5-52). In the nine tests where bedrock or the water table were not encountered, a third stratum was observed which consisted of red (2.5YR 5/6) silty clay to the base of excavation at 180 centimeters (71 inches) below surface.

Figure 5-78. Representative soil profile as observed in DT10 at Mulberry Creek.

The soils exhibited don't appear to overly represent any one soil series, but the presence of yellowish red silty clay likely represents subsoils of the Gageby soil series. This would indicate that an established A horizon is lacking at the location. None of the deep tests were positive for cultural materials, features, or paleosols.

While one planned deep test was substituted with a shovel test, the soils observed in the test appeared similar to those of nearby deep tests. This similarity suggests there was no potential for deeply buried cultural materials or paleosols to be missed by a shallower excavation. One planned test location was not accessible during the deep testing, however, based on adjacent tests DT6 and DT8, it is likely that the location would harbor the same yellowish red subsoils as encountered in those tests. Based on these results, there is no evidence for deeply buried resources within the anticipated impact depth at the Mulberry Creek permit location.

Table 5-24. Deep Test Profiles from the Mulberry Creek Project Area.

6.0 CONCLUSIONS AND RECOMMENDATION

This report details the results of pedestrian cultural resource survey of permit areas within 117.85 kilometers (73.23 miles) of the Lone Star Express II Pipeline Project - Loop 2 in Nolan, Taylor, Callahan, and Eastland Counties, Texas. The lead agency for the project is the USACE, Fort Worth District. Nearly all of the Project will be installed by open trench.

A records and literature review initiated prior to survey identified four previously recorded archaeological sites potentially intersecting USACE permit areas within Loop 2. Fieldwork on Loop 2 was conducted in the Spring of 2019 and required approximately 2,320-person hours to complete. Survey involved archaeological reconnaissance and shovel testing throughout anticipated permit areas within the Project corridor.

Fieldwork was conducted by crews affiliated with both Gray & Pape and Horizon. Fieldwork began in April and continued to May 2019. Supplemental field efforts took place in August, October, and November 2019. Intensive pedestrian survey was undertaken within 65 permit areas encapsulating a total of 29 kilometers (18 miles) of centerline and 125.9 hectares (311 acres) of APE. A total of approximately 677 shovel tests were excavated, of which six were positive for cultural material within the APE. An additional 22 shovel tests were conducted as part of resource delineation efforts. Five previously recorded resources: 41NL318, 41TA353, 41TA354, 41TA314, and 41CA27 were re-identified as a result of survey. In addition, six new previously unrecorded resources: 41TA396, 41TA397, 41TA398, 41TA399, 41CA42, 41CA43, and two isolate finds were also identified. Materials were identified adjacent to one additional previously identified resource, 41TA371, which is located outside of Permit Areas. However, these consisted of only two artifacts found on the surface in a disturbed context. Thus, the site was not expanded into current APE.

None of the identified resources are recommended as eligible for listing on the NRHP or as a SAL (Table 6-1). Four resources are of a historic age or contain a historic component: 41NL318, 41TA396, 41TA397, and 41TA399. Sites 41TA396, 41TA397, and 41TA399 consist of 1910s to 1950s historic scatters representative of trash dumps. Site 41NL318 contains the remnants of a private road/drive consisting of a raised berm and wooden bridge likely dating to the 1930s to 1950s based on available maps. The remainder of the resources are prehistoric.

Prehistoric site contents consist nearly entirely of surface scatters of artifacts, with artifact classes largely the same across each site, consisting mainly of debitage, with varying numbers of cores and bifaces. On very few occasions, a preform or more refined tool were observed. In general, the resources appear to represent raw material procurement areas due the abundant chert deposits available in the rocky soil or eroding out of nearby waterways. Activities are believed to have been largely limited to the procurement and testing of cobbles and the expedient manufacture of bifaces. While secondary and tertiary flakes were noted at a few locations, it appears that for the most part more refined tool manufacture was taking place elsewhere.

The prehistoric scatters contained few temporally diagnostic artifacts. Resources 41NL318, 41TA353/354, 41TA396, and 41TA314 contained the only diagnostic prehistoric artifacts identified during survey. Site 41TA353/354 contained Elam and Carrollton type projectile points and Site 41NL318 contained a Clear Fork Uniface, all of which can date to the middle to transitional Archaic. Sites 41TA396 and 41TA314 each contained a likely Marshall dart point which dates to the Late Middle Archaic.

Table 6-1. Summary of Resources Identified within Permit Areas of the APE.

Trinomial	Site Type	Temporal Affiliation	Research Value	NRHP Recommendation
41NL318	Prehistoric Lithic Scatter / Quarry / Historic Drive or Road	Unspecified Prehistoric	Low	Not eligible
41TA353/41TA354	Prehistoric Open Camp	Unspecified Prehistoric	Low	Not eligible
41TA314	Prehistoric Open Camp	Late to Transitional Archaic	Low	Not eligible
41TA396	Prehistoric Lithic Scatter / Historic Scatter	Late Middle Archaic / Mid-20th Century	Low	Not eligible
41TA397	Historic Scatter	Mid-20th Century	Low	Not eligible
41TA398	Prehistoric Lithic Scatter	Unspecified Prehistoric	Low	Not eligible
41TA399	Historic Trash Dump	1930s-1950s	Low	Not eligible
41CA27	Prehistoric Open Camp	Unspecified Prehistoric	Low	Not eligible
41CA42	Prehistoric Lithic Scatter	Unspecified Prehistoric	Low	Not eligible
41CA43	Prehistoric Lithic Scatter	Unspecified Prehistoric	Low	Not eligible

Table 6-2. Summary of resources Identified Outside of Permit Areas of the APE.

Trinomial	Site Type	Cultural Affiliation	Current Recommendations
41TA371	Historic scatter and prehistoric isolate	Early to Mid-20th century, Unknown Prehistoric	Ineligible

No artifacts were collected. No cultural features or historic-age standing resources were encountered within the APE. The resource areas within the pipeline corridor showed clear signs of disturbance from the adjacent pipeline ROW or past agricultural practices. Indications of soil deflation, erosion, and land modifications such as terracing, agriculture, and pond manufacture were also observed. Together, these characteristics illustrate the fact that the observed materials are displaced and thereby limit the information that could be gained from any further formal study of these resources.

One location, Mulberry Creek in Permit Area 6, was investigated by mechanical auguring to determine if the location contained soils with A horizons deeper than can be reached by shovel. However, deep testing within the APE at the location displayed a surface and subsurface that likely represent the B and C horizons of the Gageby series and produced no evidence for the potential of deeply buried resources or buried paleosols within the anticipated depth of impact at the location.

Based on the overall lack of soil deposition, few diagnostics, and lack of integrity, it is the opinion of Gray & Pape that no portion of any of the recorded resources within the proposed Loop 2 ROW retain the potential to provide significant research value and are thus recommended not eligible for the National Register, under Evaluation Criterion D or for State Antiquities Landmark status. Gray & Pape recommends no additional archaeological work for these resources or surveyed permit areas of the Loop 2 project.

		Page:	665
		Acreage:	NW/4 of Sec. 6, Block 18, T&P Ry. Co Survey
Notes:	*Nora L. Pruitt resigns as Guardian of the estates of J.H. Lowery and Lila Lowery, minors, her Children. T. O. Massey is then appointed as the Guardian. The estates owns, is an undivided 1/5 Interest into NW/4 of Sec. 6, Block 18, T&P Ry. Co. Survey*		

Grantor:	Nora Pruitt and husband O.D. Pruitt; Opal Lowery Primrose and husband, E. E. Primrose; George G. Lowery and wife, Mabel Lowery; and Ruth Lowery Shore and husband, R. E. Shore	**Document:**	Warranty Deed with Vendors Lien
		Dated:	September 27, 1943
conveyed to:		**Filed:**	March 18, 1944
		Doc. No.:	1450
Grantee:	Bob Malone	**Volume:**	324
		Page:	260
		Acreage:	NW/4 of Sec. 6, Block 18, T&P Ry. Co Survey
Notes:	*Vendor's Lien in the amount of $5,000.00 payable to The Farmers & Merchants National Bank of Merkel, Texas. Released in 222/691.*		

Grantor:	Cause No. 1538 styled Application for Guardianship of Opal Lowery, et al Minors, County Court of Jones County, Texas	**Document:**	Application for Guardianship CC
		Dated:	August 13, 1937
conveyed to:		**Filed:**	August 30, 1937
		Doc. No.:	3789
Grantee:	Mrs. Nora Pruitt, Guardian for Opal Lowery, 16 year old girl, J. H. Lowery, 13 year old boy and Lila Mae Lowery, 9 year girl	**Volume:**	277
		Page:	516
		Acreage:	NW/4 of Sec. 6, Block 18, T&P Ry. Co Survey
Notes:	*Nora L. Pruitt, formerly Nora Lowery, is the widow of G. C. Lowery who died 5/5/1938 and was the children's father. The court grants guardianship to Nora L. Pruitt, for the children's partial undivided interest in the NW/4 of Sec. 6, Block 18. G. C. Lowery's Probate was not filed in Taylor County. In the Inventory it is stated that appraised value of minors 3/10 interest in said land. In the Mechanic's Lien documents it appears Nora Lowery Pruitt, as widow of G.C. Lowery, owns 1/2 interest, then minors Opal, J. H. and Lila Mae -1/10 each, then Ruth Lowery 1/10 and George Lowery 1/10 - 2 children who were not minors, so it appears that the land was community property is Nora Lowery Pruitt owns 1/2 community interest.*
